Sodium Deficiency and Urine Chloride.—Randall and his associates report observations on acute sodium deficiency and evaluate urine electrolyte excretions, particularly urine chlorides, as a guide to parenteral sodium and chloride replacement therapy. Urine, Miller-Abbott tube drainage and other drainages were collected. Exact measurements were made, and irrigating fluids (as in Miller-Abbott tubes) were included in intake and irrigation returns included in output. Sodium deficiency states were observed in acute peritonitis, in hypertension and cardiac failure, in acute ileostomies and in patients with large fluid losses from the gastrointestinal tract with inadequate electrolyte replacement. Adequate replacement of sodium and chloride deficits is imperative. Postoperative sodium and chloride retention was also observed, with edema, hemoconcentration and oliguria appearing with excessive sodium administration. The importance of distinguishing between retention and sodium deficiency is emphasized. Ratios of urine sodium to chloride were analyzed in five groups of surgical patients. The correlation of urine sodium to chloride is high before operation in patients on standard diets and decreases significantly when these patients are given intravenous fluids preoperatively. It changes relatively little with operation. Patients who were given potassium intravenously had somewhat lower postoperative correlation than those who had not received potassium. In two groups of patients with peptic ulcers who had been subjected to partial gastrectomy, postoperative urine sodium to chloride correlation was high when there was no obstruction, but in obstructed peptic ulcers, despite normal plasma sodium, potassium, chloride and HCO_3 (blood bicarbonate) levels preoperatively, urine contained far more sodium than chloride preoperatively. The reverse was true postoperatively, and correlations were poor. Patients who were seriously ill after major surgical intervention showed poor correlation of urine sodium and chloride excretion. Estimation of sodium and chloride excretion and replacement by measurement of urine chlorides alone in major surgical cases is inadequate and may be dangerous. Quantitative determinations of individual ions in blood, urine and drainage are essential if the fluid and electrolyte balance is to be maintained.

Lumbodorsal Sympathectomy for Hypertension.—Simeone and Ramirez discuss responses to sympathectomy other than those of the blood pressure. Such responses are surprisingly few. There is an increased sensitivity to insulin occurring long after sympathectomy. The total blood and plasma volumes are slightly decreased long after lumbodorsal sympathectomy, but the changes are not large enough to warrant attributing to them the effects which sympathectomy exerts on the blood pressure. The ability of the kidneys to clear the blood of mannitol and sodium paraaminohippurate is nearly normal in patients with only moderately severe hypertension, but is severely impaired in patients with severe hypertension. A close correlation exists between the degree of histological change in the kidneys and their ability to excrete mannitol and sodium paraaminohippurate. Patients whose blood pressure was improved one year after sympathectomy had nearly normal renal clearances; those who were not improved by sympathectomy showed preoperative values which were nearly one-half the normal. The filtration fraction was elevated both in the patients whose blood pressure improved after sympathectomy and in those whose blood pressure was unchanged. Among the former, however, the filtration fraction was decreased by sympathectomy; among the latter, the filtration fraction remained unchanged or increased. The data presented suggest that, in hypertensive patients with pronounced impairment of the rate of glomerular filtration and renal plasma flow, lumbodorsal sympathectomy does not cause a lowering of the blood pressure. A high filtration fraction, per se, however, does not preclude a favorable result.

Cryptococcosis.—According to Ratcliffe and Cook, cryptococcosis is a chronic or subacute infection that may involve any part of the body, but that has a special predilection for the brain and meninges. The authors found 127 cases of cryptococcosis in the literature, to which they add one of their own. Their patient, a man aged 30, was admitted to the hospital because of roentgenographic evidence of a pulmonary lesion. The only complaint was pain of one day's duration in the right lower portion of the chest that occurred one month before admission. The chest was resonant throughout. Auscultation revealed a few high-pitched, sibilant rales. Spinal fluid examination gave normal results, but india ink preparation of the sputum revealed numerous yeast cells with a clear halo, presumably Cryptococcus neoformans. Sputum cultures from the same specimen revealed budding cells with halo-like capsules, morphologically characteristic of C. neoformans. Intraperitoneal injection of washings from these cultures into white mice caused death within eight days of all animals that had received injections. C. neoformans was found in them at autopsy. The patient complained of a headache. Subsequently, spinal punctures showed increasing pressures and india ink preparations of the fluid yielded organisms morphologically characteristic of C. neoformans. The patient died one month later. Necropsy revealed that the lesions were largely confined to the lungs and the brain. Pulmonary lobectomy had at first been considered for this patient, because the roentgenogram of the chest and the finding of C. neoformans in the sputum were the only indications of cryptococcal infection. Sensitivity testing showed C. neoformans to be sensitive to polymyxin in vitro, but the infection did not respond to treatment with this drug. Penicillin, streptomycin, sulfadiazine and potassium iodide were used without success. The authors feel in cases of pulmonary involvement of localized nature, in the absence of systemic spread, the involved lobe of the lung should be surgically removed.

Motion Sickness.—Harbert and Schiff believe that motion sickness cannot be ascribed to a single organ. It is the result of a break in accommodation by the spinal and medullary centers from continual unusual stimuli arising in many organs. In the order of importance, the vestibular, proprioceptive, visual and the other senses are involved. Stimuli from various organs normally cause automatic adjustments of the body to changes in its relation to the force of gravity. These sensations are correlated and integrated in cerebellar, medullary and spinal centers. When these centers are repeatedly subjected to unusual stimuli, a point is reached where they cause more than the proper reflexes. A spilling over to other medullary and higher centers occurs and produces symptoms of motion sickness. Symptoms of motion sickness are influenced by psychic factors, such as memory, association and fear. In airsickness, especially, the unsatisfactory rationalization of fear is a great factor. Symptoms of seasickness vary. In the treatment, general hygienic measures a day or two before sailing with avoidance of last minute parties, bustle and nervous tension are advantageous. If one lies down with the eyes closed or reclines in a deck chair facing away from the sea, both visual and skeletal reaction to stimulation will be reduced. Good ventilation and absence of odors are helpful. Physical exertion tends to reduce the tendency to lethargy. Atropine, scopolamine (hyoscine) hydrobromide and hyoscyamine have been prescribed because they inhibit the vagus or parasympathetic nerves. The barbiturates, preferably one of the quick-acting ones such as secobarbital (seconal®) sodium or pentobarbital (nembutal®) are probably useful adjuncts in the early phases; besides alleviating apprehension and worry, they reduce the sensitivity of the medullary centers and so facilitate adjustment. Pentobarbital is excellent when the motion of the ship produces insomnia. Dimenhydrinate (dramamine) has proved highly satisfactory in the prophylaxis as well as in the treatment of motion sickness.

*Lipoid Pneumonia Due to Use of Mineral Oil as Laxative. E. Baron.—p. 448.
Obstetrical Factors in Infant Mortality. E. S. Groseclose.—p. 451.
Tuberculosis Control Program in General Hospital. E. C. Harper and W. E. Roye.—p. 455.

Lipid Pneumonia Caused by Mineral Oil Laxative.—According to Baron, lipid pneumonia can be classified as a man-made disease. Oil in nose drops, in vitamins or in a mineral oil laxative can cause this condition. Cases of lipid pneumonia in young children are understandable in view of the fact that the administration of oily vitamin preparations is frequently associated with struggling and possible aspiration. Most fish oils and free fatty acids are the more irritating types for pulmonary tissues. Mineral oil is not assimilable; being a saturated hydrocarbon, it cannot be digested in the body and, consequently, remains in the lungs indefinitely, except for the small amounts which appear in the sputum. Anatomic defects in the mouth, palate, tongue, larynx or esophagus, neurological disturbances that interfere with swallowing, the use of forced feedings and the fact that mineral oil, being bland, does not initiate the cough reflex, are factors that predispose to the aspiration of oil. When mineral oil reaches the dependent portions of the lungs, it first remains free in the alveoli but is later picked up, in droplets, by the macrophages. Some of the mineral oil can be disposed of in the sputum, and a small amount reaches the lymph nodes, but the bulk remains indefinitely in the lung, where it causes the development of fibrous tissue. This renders the lesion detectable by roentgen ray. The lower lobes, particularly the right, are most likely to be involved. The abnormal lung is a fertile soil for repeated attacks of bronchopneumonia, which may be responsible for the death of the patient. The author presents histories of six patients in whom necropsy disclosed lipid pneumonia. All had received mineral oil as a laxative, but death had been caused by other conditions. Since oil cannot be removed from the lungs, prevention is the only treatment. Laxatives containing mineral oil should not be used, nor should oily nose drops be instilled in the respiratory tract.

Gastric Ulcer After Vagotomy.—According to Morrissey, the literature records three instances of gastric ulceration developing after successful vagotomy for a duodenal ulcer. These three instances occurred in a total of 268 patients subjected to vagotomy. The complication appears to be rare but is important because of the malignant potentiality of gastric ulcers and because these ulcers are sometimes remarkably painless after vagotomy. The author reports two additional cases, which provide further evidence of the inefficacy of vagal section in interrupting the course of gastric ulceration. These two cases were reported from a series of 79 patients with duodenal ulcer who were treated by vagotomy alone. In both cases the gastric ulcer developed within six months of vagal section. Morrissey believes that vagotomy is unsuitable as a treatment of gastric ulceration and that it does not confer protection against the development of gastric ulceration.

*Irreducible Intussusception Due to Meckel's Diverticulum: Report of Case with Recovery in Infant of Eight Months Old. J. Aitken.—p. 255.
*Benign Spontaneous Pneumothorax: Study of 70 Cases. A. G. Melrose.—p. 263.

Intussusception Due to Meckel's Diverticulum.—Aitken reports an eight month old infant with an irreducible intussusception caused by a Meckel's diverticulum. Treatment consisted of resection of the involved segment of the bowel and side to side anastomosis. The child recovered. This treatment is probably the best for an irreducible enteric intussusception. Detailed examination of the symptoms and signs does not suggest any method of differentiation between this type of intussusception and the usual enterocolic type when the patient is an infant, although the previous history and duration of the symptoms may be helpful.

Benign Spontaneous Pneumothorax.—Melrose presents a study of 70 cases of benign spontaneous pneumothorax by the follow-up method, with particular reference to etiology and to the subsequent incidence of pulmonary tuberculosis and of recurrence. The 70 patients were admitted for treatment of benign spontaneous pneumothorax to the medical wards of two Glasgow hospitals in the ten year period 1939-1948. They were asked to report for clinical examination, interrogation and chest roentgenogram, and 58 responded. The remaining 12, who were unable or unwilling to come to the hospital, provided the desired information by letter, telephone or to a social worker. Of the 70 patients, 65 were males. Physical exertion is not considered an important factor in the causation. Twenty-three per cent of the cases were recurrent. Pulmonary tuberculosis developed in four patients. If the unduly high incidence of pulmonary tuberculosis in the Glasgow area is taken into consideration, it may be assumed that tuberculosis is no more likely to develop in a person with benign spontaneous pneumothorax than in the average person in the general community. Spontaneous pneumothorax was not associated with any special type of physique. There were no familial cases.

Residual Osteitis of Alveolus of Maxilla as Cause of Facial Pain. P. S. Meyrick and L. S. Manion.—p. 507.

Perceptive Deafness and Neonatal Jaundice.—Gerrard reported 22 patients with kernicterus due to Rh isoimmunization who were over three years of age; the oldest was 23 years of age. Crabtree subjected 18 of these patients to a thorough otological examination. The remaining four were too backward mentally to permit an audiometric examination. These four patients can hear, but the toneless speech of one of them suggests a perceptive deafness in the range of high frequencies. Two additional patients with kernicterus, unassociated with Rh incompatibility, were examined audiometrically and proved to have perceptive deafness. Among the aforementioned 18 patients, there were 14 with perceptive deafness, two being completely deaf. Thus, 16 of 24 patients with kernicterus had perceptive deafness. The authors point out that there are a large number of cases of perceptive deafness of obscure origin. When Carruthers focused attention on the relation between maternal rubella during the first three months of pregnancy and deafness of the child born subsequently, it was hoped that the number of these cases might be noticeably reduced. It has now been shown that some of these cases are associated with a severe neonatal jaundice; this jaundice is usually but not invariably due to Rh isoimmunization. This type of deafness differs pathologically from that associated with maternal rubella, for rubella prevents or hinders the normal development of the primitive cells forming the organ of Corti, whereas in deafness associated with kernicterus the organs of hearing develop normally but the cochlear nuclei are damaged. Crabtree and Gerrard stress that perceptive deafness, usually of high tone type, is common in kernicterus. The severity of the deafness bears no relation to the severity of the other disabilities. All patients with kernicterus should be examined by pure tone audiometry. Assessment of intelligence in cases of kernicterus should be made in the light of the otological findings, and the type of intelligence tests selected accordingly. A history of severe neonatal jaundice may be obtained in some cases of perceptive deafness of unknown cause dating from early childhood.

*"Medical Sympathectomy" in Hypertension: Clinical Study of Methonium Compounds. R. Turner.—p. 353.
*Pentamethonium in Hypertension. S. Saville.—p. 358.

"Medical Sympathectomy" in Hypertension.—According to Turner, the hexamethonium and pentamethonium compounds block the transmission of nerve impulses through autonomic ganglions. The author reports on the effects of pentamethonium (or hexamethonium) iodide (or bromide) when given by intravenous injection to hypertensive patients, on the effects of intramuscular injections and on oral therapy. Several case histories are presented that illustrate some of the difficulties encountered in this form of treatment. The author concludes that the methonium drugs have as yet no place in the routine management of patients, though they may prove useful in the treatment of resistant symptoms related to hypertension. More information is needed about their precise action, and for the present it will be most profitable to study their effects in patients who might otherwise be treated by sympathectomy. There is no evidence as yet that continuous reduction of blood pressure by drugs which paralyze the autonomic ganglions will prove beneficial to hypertensive patients, and it may prove harmful to some. There is no reason to doubt that other more efficacious and perhaps more selective preparations will be made, and possibly a study of the methonium compounds will throw light on the etiology of essential hypertension.

Pentamethonium in Hypertension.—Saville says that his present practice is to test the initial response to pentamethonium salts by giving one or two doses of 50 mg. intramuscularly and then to start daily treatment by mouth. The oral dosage varies, but is usually 0.5 to 1.0 Gm. every four, six or eight hours. The first dose should be taken as early as possible in the day. No significant therapeutic difference between the bromide and the iodide salts was observed. The drug is most conveniently taken in the form of flavored aqueous solution. Results obtained with pentamethonium in five patients suggest that pentamethonium bromide may be useful in the treatment of at least some forms of hypertension. It relieved troublesome symptoms in all these cases and apparently arrested the progress of the disorder. The initial improvement obtained with pentamethonium was maintained in all but one of the five patients. The condition of this patient was so grave that symptomatic relief was the most that could be expected. Time alone will show whether pentamethonium can reverse a steadily progressive condition, but it is conceivable that early and assiduous treatment will improve the prognosis.

Pneumonokoniosis in Queensland Foundries. D. Gordon.—p. 217.
Some Practical Aspects of Venereal Disease. N. D. G. Abbott.—p. 224.

Ratio of Large to Small Lymphoid Cells in Lead Poisoning.—Shiels cites a report by Ferguson and Ferguson, which revealed that in men exposed to lead there is an increase in the ratio of large lymphocytes plus monocytes to small lymphocytes. The Fergusons believed that the increase in the percentage of large mononuclear cells was more closely related to the clinical condition than was the stippled cell count, the blue line, the red cell count or the percentage of hemoglobin. Shiels was able to confirm the observations made by the Fergusons in an earlier investigtion. In a study of 400 employees of a new plant producing storage batteries, he again found confirmation of the report of the Fergusons. In cases of lead poisoning, the ratio of lymphoid cells falls again to within the range of the ratio for unexposed persons. If the ratio falls to less than 2, lead poisoning is imminent if not already present. Recovery from lead poisoning is accompanied by a rise in the ratio to above 2 in the early stages. In the later stages of recovery the ratio again falls to the range of ratios of unexposed persons. In the case of new workers, there is a direct correlation between the cell ratio and the urinary lead concentrations as exposure increases. The cell ratio is a valuable guide to the prevention and diagnosis of lead poisoning.

Stevens-Johnson Syndrome.—According to Loewenthal and his associates, the condition which in the English literature is now generally called Stevens-Johnson syndrome has also been designated as erythema exudativum multiforme with pneumonia, ectodermosis erosiva pluriorificialis and dermatostomatitis. The cutaneous lesions probably represent an allergic reaction to a variety of substances, bacterial, fungal, viral or chemical. The condition behaves as a specific infective one, with involvement of the skin, eyes, mucous membranes and lungs. The disease may last 10 days to four weeks or more, and some survivors are left with permanent ocular damage. The authors present the histories of two patients with this disorder, a woman aged 53 and a 10 year old boy. In both patients the disorder responded within 48 hours to treatment with aureomycin, whereas sulfadiazine and penicillin therapy had failed. The favorable response to aureomycin therapy agrees with the observations reported by others, and the authors believe that aureomycin acts as a specific remedy in this disease.

Cancer Cells in Prostatic Secretion.—Jönsson and Fajers report on 110 patients with various prostatic disorders admitted to the Lund Surgical Clinic. Study of prostatic secretion according to the method of Papanicolaou made a diagnosis of cancer possible in 16 of the 110 cases. In 11 others, cancer was suspected, and in five of these the diagnosis was later verified. Two cases, which on the basis of the cells in the secretion were first given diagnosis of hypertrophy, were subsequently established as cancer. Diagnosis was correct in nearly 90 per cent of the cancer cases in which adequate amounts of secretion could be obtained. The authors feel that search for cancer cells in the secretion has afforded such encouraging results that it should be included as a routine method in diagnostic measures in cancer of the prostate.

Tibial Graft as Retrosternal Support in Funnel Chest.—According to Wahren, the indications for surgical correction of a funnel chest are those of a disturbance of the cardiac function, the cosmetic considerations and the mental attitude of the patient with regard to the malformation. He describes the case of a girl, aged 10, with a funnel chest deformity since birth, in whom the depression of the chest had become more pronounced, so that during the last year she suffered from dyspnea. The lower part of the sternum was depressed to the depth of about 4.5 cm. Wahren describes a new type of operation that he used in this case. He employed a tibial graft, which was inserted under the elevated sternum to keep the latter in the desired position.

Blood Picture in Bacterial Endocarditis.—According to Dammert, subacute bacterial endocarditis is a typical example of an infectious disease that causes anemia. Some investigators assume that infectious anemias are due to iron deficiency. Knisely found that an intravasal agglutination occurs in infections and that the blood cells in such agglutinations are dissolved by the phagocytes in the liver and the spleen to such an extent that anemia results. Of 54 patients with bacterial endocarditis reported by Dammert, 38 were treated with penicillin. About half the patients died in the hospital during the treatment. The cause of death was congestive heart failure, thromboembolism or relapse. A close connection could be established between the course of the endocarditis and the anemia. Penicillin therapy usually brings about an improvement in the blood picture, whereas other treatments usually impair it. A daily dose of 300,000 units of penicillin gave better results than a smaller amount. Congestive heart failure impedes recovery. It is difficult to assess the effect of penicillin in patients with this condition. Signs of continued infection remain. Knisely's theory may offer an explanation. Severe subacute bacterial endocarditis is accompanied by intravasal agglutination. Red blood cell aggregates appear in the vascular bed and impede the local blood stream, causing injury to the vascular walls, leakage of fluid, and extravasation of red blood corpuscles into the tissue. This so-called "sludge-factor" of the blood concurs with other factors, which also cause loss of fluid through the endothelium. In patients with edema, large aggregations of blood corpuscles, delayed blood flow, loss of plasma and hemoconcentration are observed. It may be assumed that the penicillin has prevented bacteremia but has not counteracted the sludge-factor, which is maintained by the heart failure. Thromboembolic processes are common. Hemorrhages and alimentary factors may also play a part in the causation of anemia.

*Possibility of Preventing Transfusion Syphilis by Chemotherapy. R. Fussgänger.—p. 1024.

Thiosemicarbazone in Treatment of Tuberculous Empyema. H. Wagener. —p. 1031.

Arsenoxides to Prevent Transfusion Syphilis.—Brock and Conradi used fresh, citrated blood, to which an arsenoxide preparation had been added to prevent the transmission of syphilis, for transfusions in 661 infants and 278 children. The blood was usually given in divided transfusions, over two or three days. No undesirable secondary effects were observed. The clinical effect of the transfusion was not altered, and there was no significant difference in the resistance of the erythrocytes in three day old citrated blood, whether or not the arsenoxide preparation had been added.

Prevention of Transfusion Syphilis.—The increased use of blood transfusion and the greater incidence of syphilis have directed attention to the danger of transmitting syphilis in this way. According to Fussgänger, the literature contains records of more than 100 cases of transmission, and he assumes that many others have not been reported. The fact that it is difficult to demonstrate syphilis during the first six weeks after infection has taken place is largely responsible for the transmission of syphilis by transfusion. Efforts have been made to prevent this transmission by adding spirocheticidal substances to transfusion blood. Since experimentation with the syphilis spirochete proved difficult, the spirochete of recurrent fever was employed. It was found that these spirochetes remain viable and virulent for several weeks in stored blood. Certain arsenoxides kill the spirochetes in a short time, and the quantities required are so small that no harmful effects need be feared in the recipient of the blood. The clinical application of this procedure is being investigated.

*Indications for Splenectomy in Children with Essential Thrombopenia. T. D. Stahlie.—p. 64.

Gangrene After Scarlet Fever.—Bethe cites a 5 year old girl in whom gangrene of both legs developed after an attack of scarlet fever. It was decided to amputate the left leg 8 cm. below the groin. Following the amputation, the general condition of the child improved rapidly and necrotic tissue sloughed off the right leg. The child could be discharged after five months with a temporary prosthesis. The author reviews the literature on the occurrence of gangrene of the extremities after scarlet fever.

Splenectomy in Essential Thrombopenia in Children.—Stahlie discusses the pathogenesis of essential thrombopenia in children and reviews the various treatments, pointing out that splenectomy is the only causal therapy. He shows on the basis of seven case histories that splenectomy is rarely indicated in children, as the disease shows a tendency to spontaneous cure even after long periods (more than two years). Splenectomy should not be done in cases of simple hypoplasia of the megakaryocytes.

*Antabuse in Treatment of Chronic Alcoholism. A. Marti-Granell and J. M. Pedrosa.—p. 122.

Antabuse®.—Marti-Granell and Pedrosa report on tetraethylthiuram disulfide (antabuse®) therapy combined with psychotherapy in seven alcoholics. A daily dose of 0.75 or 0.25 Gm. of this drug was well tolerated by the patients for three to four months, during which time the desire to drink in the patients was not manifest or was controlled by the patient, who himself requested further administration of the drug. Four patients complained of asthenia, paresthesia and neuritic pain. These complaints disappeared after administration of thiamine in the course of psychotherapy. The authors direct attention to the fact that tetraethylthiuram disulfide is well tolerated but may be harmful. The drug should be given only by a physician. It should be sold only to physicians.

Vitamin E and Blood Sugar.—Levens and Rösgen cite earlier reports indicating a connection between vitamin E and sugar metabolism and point out that if this vitamin acts on the blood sugar regulating centers in the hypophysis or the diencephalon, then it should produce an increase in the blood sugar level. They studied the effect of alpha tocopherol in women who had been hospitalized for such disorders as hypertension, cholecystopathy, bronchitis, adnexitis, heart lesions and cervical polyps, but who had no disturbance of the carbohydrate metabolism. The fasting blood sugar curves of these women were ascertained before and after injection of isotonic sodium chloride solution. Then 60 mg. of alpha tocopherol was injected, and following this the blood sugar content was determined at half hour intervals. Tolerance tests were then made with dextrose, epinephrine and insulin. Either immediately or 24 hours before the tolerance test, 60 mg. of alpha tocopherol was given. In seven of 29 patients the fluctuations in the blood sugar were so slight after the injection of vitamin E that they differed little from the "empty" blood sugar curves (no injection or only isotonic sodium chloride solution). The blood sugar values in all the other women tested showed deviations averaging 40 per cent from the normal. All women finally showed a decrease, but in a few instances this was preceded by an increase. The authors ascribe this increase to counterregulatory influences. The changes after epinephrine and dextrose tolerance tests were similar. The blood sugar values were usually higher; the peak was reached faster, and the decrease was slower than without administration of the alpha tocopherol. Moreover these effects were usually more pronounced when the vitamin had been given immediately rather than 24 hours before the tolerance test. The insulin tolerance tests disclosed an inhibition of the blood sugar decreasing effect. The authors conclude that administration of the vitamin influences the blood sugar level by rendering it more unstable, with a tendency toward reduced values. Its point of attack has not been ascertained, and there were no indications of a direct influence on the diencephalohypophysial system. The authors believe that the level of the vitamin E content in the blood plays an important part in the peripheral phases of carbohydrate metabolism.

Constitutional Changes in Chronic Tuberculous Meningitis.—Schönenberg points out that deafness, blindness, spastic paralysis and other defects were observed in patients who have survived tuberculous meningitis after streptomycin therapy. Such sequelae have usually been ascribed to incorrect dosage or inadequate purification of the antibiotic. In the Italian literature Bulgarelli called attention to somatic constitutional changes as the result of the disease itself. Schönenberg made similar observations on two children, aged 9 and 6. Adiposity of the type observed in Cushing's disease or in adiposogenital dystrophy developed in these children during their convalescence after tuberculous meningitis. In one child, adiposity was associated with striae distensae and osteoporosis. The other child had neither osteoporosis nor striae but a genuine adiposogenital dystrophy, and there were psychointellectual changes; intelligence was somewhat retarded, and silly behavior predominated. Extreme forms of obesity have been noted after encephalitis. The so-called tuberculous meningitis is really, particularly when treated with streptomycin, a tuberculous encephalomeningitis. Either certain hypophysial or diencephalic centers might have been involved in the disease process, or changes in blood perfusion and deficient function may have resulted from the vascular changes caused by tuberculous meningitis. Bulgarelli's assumption of pressure produced by the dilated third ventricle are less valid.

*Appendicitis and Pregnancy. F. J. J. van Assen.—p. 171.
Lower Nephron Syndrome. G. A. Lindeboom.—p. 183.
Cystic Degeneration of Ovaries. B. H. Wormgoor.—p. 201.

Appendicitis and Pregnancy.—According to van Assen, the history provides the most reliable diagnostic data in appendicitis occurring during pregnancy. The appendix in pregnancy becomes displaced, so that the tip almost reaches the costal arch. As the result of this dislocation, the point of tenderness is also changed. During the early period of pregnancy, the symptoms are not much different than the usual ones, but as pregnancy advances, the picture changes. The point of tenderness is now higher up, and Rovsing's sign is rarely elicitable. Diarrhea or constipation are of no diagnostic importance here. Laboratory data are likewise of little value. Leukocytosis, for example, normally occurs in pregnancy. The following conditions must be considered in the differential diagnosis: extrauterine pregnancy, salpingitis, abortion and torsion of an ovarian tumor during the early part of pregnancy; and pyelitis, renal or ureteral calculi, ileus and disorders of the gallbladder during the advanced stages of pregnancy. The most frequent complication of appendicitis during pregnancy is abortion. In simple appendicitis the incidence has been estimated at 11 per cent, in the presence of an abscess at 66 per cent and in the presence of a diffuse peritonitis at 72 per cent. The author presents four case histories and suggests that treatment today can be conservative. Cesarian section is no longer necessary, since the administration of chemotherapeutics or antibiotics, of progesterone and estrone and the use of gastrointestinal decompression make the prognosis much more favorable for both mother and child. Simple appendectomy is the method of choice.

*Wilms' Tumor in Children. Review. A. K. F. Jacobsen.—p. 1229.
*Fibrosarcomas and Their Prognosis. G. F. Saltzmann.—p. 1235.
Cytological Diagnosis of Bronchial Cancer. H. Lindeman.—p. 1240.
Six Cases of Wilms' Tumor in Children. A. K. F. Jacobsen.—p. 1244.
Nevus Epithelioma Cylindromatosus with Dominant Inheritance Through Four Generations. R. Weyde.—p. 1249.

Wilms' Tumor in Children.—Jacobsen says that the literature records about 1,200 cases of Wilms' tumor. The tumor occurs most often between the ages of 2 and 3, rarely after the fifth year, is found equally often on the right and the left side and is seldom bilateral. It varies in size from small nodes in the renal substance to tumor formations occupying half the abdominal cavity. It is well circumscribed and metastatizes late, through the venous system. In about 70 per cent of the cases medical aid is sought because of the tumor, in not quite 10 per cent because of hematuria, in some cases because of atypical symptoms; in about 20 per cent, pain is the initial symptom. The results of examination of the blood and urine are uncertain. Differentiation from other retroperitoneal tumors, particularly neuroblastomas, may be difficult. Biopsy is cautioned against because of the risk of spread along the puncture line and damage to the barrier formed by the tumor capsule, while unnecessary manipulation of the tumor may facilitate passage of tumor cells into the blood vessels. Because of the insidious nature of the disease, early diagnosis is made in only about 5 per cent of the cases. Transperitoneal nephrectomy is recommended as the standard surgical method. Authors do not agree as to the advisability of preoperative roentgen treatment, but there is some agreement that it should be used postoperatively. Radium treatmen has been given in but a few cases and without success. Untreated cases are fatal in the course of less than one year. The shorter the duration of the disease the better the prognosis. In more than half the patients surviving five years, the onset occurred in the first year of life. There is no relation between the size of the tumor and the chance of recovery. Metastases to the lungs need not make the condition hopeless. The prognosis is better in tumors of predominantly epithelial structure. Recurrence is seen in about 80 per cent of the cases in the first year after operation. About 5 per cent of the patients survive five years or more.

Prognosis of Fibrosarcomas.—Saltzmann reports on 80 cases of fibrosarcoma treated from 1936 to 1948. The sexes were equally represented. Thirty-six patients are well, 21 of these after a five year observation period. Half the patients who died lived one year after diagnosis. The 16 cases with certain metastases at the start of treatment were all fatal. In 24 patients, the tumor recurred after attempted radical treatment; 10 of these were well after five years. Multiple fibrosarcomas occurred in only three instances. Microscopically, the tumors vary in the general tissue structure, with transitions between bundle structures, which have oblong cells, and homogenous structures, which have round cells. To a certain extent, fibrosarcomas connected with the skin are thought to be of bundle structure type, and those not associated with the skin, of homogenous structure, which in some cases has been found to develop from bundle structure. Whether all fibrosarcomas develop in this way is not known. The prognosis is more favorable in fibrosarcomas localized to the skin. Increased cell polymorphism and occurrence of giant cells and of mitoses are unfavorable prognostic signs. The prognosis is often unfavorable in tumors with coarse granulation of the nucleus. Radical surgical intervention is the best form of treatment. Nearly all patients operated on received postoperative radiotherapy, usually in fractionated doses. In all inoperable conditions, fractionated roentgen treatment was given. Radium intubation proved applicable in the treatment of small superficial fibrosarcomas, in practically all of which, however, radical surgical treatment is possible. This material supports the general view that fibrosarcomas are highly resistant to roentgen treatment, yet two patients given only roentgen therapy are free from symptoms after an apparently satisfactory observation period. The tumors in these patients were in the thoracic wall and accessible to large roentgen doses.

*Venous Thrombosis: Anticoagulant Therapy. G. Zannini.—p. 997.
Encephalitis and Streptomycin in Relation to Grippe Infection. A. Pani.—p. 1005.

Anticoagulants for Venous Thrombosis.—Zannini reports a case of phlebothrombosis in a woman aged 50 years following a panhysterectomy. Combined anticoagulant therapy with heparin sodium and bishydroxycoumarin (dicumarol®) was instituted immediately after the appearance of the first symptoms of thrombosis and was continued for 30 days. For the first four days, 250 mg. of heparin sodium was given daily, and the heparin treatment then was continued with 80 to 110 mg. per day. The total dose administered was 3,875 mg. On the first day, 300 mg. of bishydroxycoumarin was given, 200 mg. on the second day and 100 mg. on the following days, up to a total dose of 2,000 mg. Treatment with 400,000 units of penicillin daily had been practiced before the institution of the anticoagulant therapy and was continued simultaneously with the administration of the anticoagulants. A clotting time of from 10 to 26 minutes could be maintained. The maximum prothrombin time obtained was 49 seconds. Pain subsided within 72 hours, while edema still persisted. Definite progressive improvement occurred from the sixth to the twentieth day. Roentgenologic examination at the end of this period revealed an extensive obstruction of the deep vascular trunks of the leg, while repeated roentgenologic examination on the thirtieth day showed that these vascular trunks were recanalized in their entire length. Edema had disappeared, and tracings of the venous pulse were normal. The anticoagulants not only arrest the spread of the thrombotic process but also dissolve the clot and may induce canalization of the vessels involved.

Problem of Improving the Results of Systematic Roentgenologic Detection of Pulmonary Tuberculosis. M. Bariéty and C. Coury.—p. 973.
**Syndrome of Hypotony of Biliary Tract: Results of Surgical Treatment.* P. Mallet-Guy and L. Durand.—p. 974.
*Therapeutic Trial with Streptomycin in Infectious Jaundice. J. Marassi, M. Amedeo and P. Sassi.—p. 976.

Surgical Treatment of Hypotony of Biliary Tract.—Mallet-Guy and Durand report 135 patients with hypotony of the biliary tract who were subjected to right splanchnicectomy by the subdiaphragmatic route. The operation was performed under manometric and roentgenologic control. Of the 135 patients, 104 were followed for one to nine years. Satisfactory results were obtained in 82.2 per cent; improvement resulted in 5.2 per cent, and 12.6 per cent were therapeutic failures. Biliary hypotony is characterized by abnormally low manometric curves, refractory pain in the region of the gallbladder and, occasionally, attacks of fever and jaundice. Severe dyspepsia and headache complete the clinical picture. The patients are frequently referred to the surgeon with a diagnosis of a syndrome of the common biliary duct, chronic pancreatitis and gallbladder lithiasis. Cholecystectomy is only occasionally indicated for lesions of the gallbladder, while right splanchnicectomy is the method of choice for interrupting the delicate, inhibitory fibers of the muscular apparatus of the biliary tract, particularly in cases of "gallbladder stasis" refractory to medical treatment. Diagnosis of biliary hypotony may be suggested by cholecystography, although the roentgenologic appearance of stasis in the course of a spastic condition of the biliary sphincters may be the same as that of biliary hypotony. When the hypotony is associated with biliary lithiasis, the diagnosis can be established only in the course of a surgical intervention, after puncture of the gallbladder or catheterization of the cystic duct.

Streptomycin in Infectious Jaundice.—Marassi and co-workers treated with streptomycin 10 adult patients, three with epidemic jaundice, four with angiocholecystitis, one with colon bacilli bacteremia and icterus, one with alcoholic cirrhosis and icterus and one with a terminal hepatonephritis. One gram of streptomycin was given daily in divided doses of 0.25 Gm. every six hours for 12 to 15 days. Rapid drop in temperature, pronounced diuresis, disappearance of icterus and frequently a spectacular improvement in the general condition resulted in all the patients except the one with hepatonephritis, in whom treatment was instituted too late. Streptomycin therapy was used in some of these cases after penicillin had failed. The effect of streptomycin was superior to that of penicillin. This was probably due to the multivalent activity of the streptomycin against the bacteria that cause icterogenic septicemia as well as against the bacteria of the biliary tract. Chances for a complete recovery are better the earlier the treatment is instituted. No toxic effects were observed with the dose of 1 Gm. of the drug per day.

*Nontraumatic Subarachnoid and Cerebral Hemorrhage: Neurosurgical Aspects. E. Ley, S. Obrador and P. Urquiza.—p. 384.

Nontraumatic Cerebral Hemorrhages.—Ley and collaborators state that subarachnoid and cerebral hemorrhages in young adults are due, in the majority of cases, to spontaneous rupture of congenital cerebral arterial aneurysm or to congenital cerebral arteriovenous angioma, which can be seen by arteriography and can be treated surgically. They describe the neurological symptoms and arteriographic aspects in three series of patients, which included eight cases of repeated subarachnoid hemorrhage from rupture of aneurysm of the internal carotid artery or of its branches, one case of cerebral hemorrhage into the ventricles from spontaneous rupture of a cortical arteriovenous angioma of the middle cerebral artery and one of a spontaneous intracerebral hematoma. Prognosis of cerebral and subarachnoid hemorrhages in young persons is poor, especially i the hemorrhages are repeated. Cerebral arteriography followed by surgical intervention is indicated. In the reported cases, the surgical treatment consisted in (1) ligation of the common carotid artery followed by operation as indicated, in the treatment of a subarachnoid hemorrhage due to rupture of a cerebra arterial aneurysm; (2) ligation of abnormal blood vessels and extirpation of the arteriovenous angioma, and (3) aspiration o blood and blood clots and left frontal lobectomy in left frontal hematoma. The operation is one of emergency, especially if the patient is in coma.

Comparative Study of Metabolic Effects of ACTH and Cortisone. R. S. Mach, P. Ducommun, J. Fabre and others.—p. 691.
*Sympathectomy and Peptic Ulcer. B. Steinmann.—p. 695.
*Effect of Rutin on Blood Coagulation in Regard to Therapy and Prophylaxis with Dicumarol and Its Derivatives. P. Matis, H. Funfack and C. Rockstroh.—p. 701.

Sympathectomy and Peptic Ulcer.—Steinmann reports a woman aged 19 with essential hypertension (210/110 mm. of mercury) due to hypoplasia of the left kidney. Permanent lowering of blood pressure to values varying from 90/65 mm. to 120/85 mm. of mercury resulted from bilateral sympathectomy and splanchnicectomy according to Smithwick's technic. Fifteen months later, severe hemorrhages from a large gastroduodenal ulcer required gastrectomy. History and microscopic examination of the ulcer tissue revealed that ulcer attacks had occurred repeatedly before the sympathectomy and splanchnicectomy had been performed, but without severe complications. This case as well as others in world literature demonstrate that bilateral splanchnicectomy may induce severe ulcer complications, particularly bleeding, in patients with an ulcer in whom bilateral splanchnicectomy had been performed for hypertension. Severe complications of peptic ulcer developed unnoticed because normal epigastric pain sensations were greatly reduced and the vasoconstrictor effect of the sympathetic nerves on the arteries in the splanchnic nerve area was abolished. The vagus tone predominated because of the abolition of the sympathetic counterregulation.

Effect of Rutin on Blood Coagulation.—Matis and co-workers administered to 20 rabbits 50 mg. of rutin per kilogram of body weight by intramuscular route for 40 days. The clotting time and the prothrombin values were determined before, during and after the administration of rutin. The injections did not cause significant changes in the clotting mechanism of the rabbits' blood. Ten rabbits were fed 8 mg. of bishydroxycoumarin (dicumarol®) per kilogram of body weight and then were given injections of 50 mg. of rutin per kilogram of body weight for 30 days. A dose of 8 mg. of rutin per kilogram of body weight was given once more after rutin had been discontinued. There was no significant difference in the response o bishydroxycoumarin before and after the administration of rutin. Intravenous injections of 400 mg. of rutin for 14 days did not produce any significant changes in 15 patients, in whom the clotting time, retraction time and prothrombin time were determined. Lowering of the prothrombin level to 30 to 45 per cent of the normal level was observed in all the patients after administration of therapeutic doses of 250 mg. of bishydroxycoumarin on the fifteenth and sixteenth day. Results suggest that administration of rutin is justified in the course of anticoagulation therapy with bishydroxycoumarin to prevent capillary damage. Rutin thus makes it possible to employ bishydroxycoumarin in treatment of hypertensive patients, of diabetics, arteriosclerotics and persons of far advanced age.

*Significance of Bronchial Changes Caused by Tuberculous Bronchial Lymph Nodes Regarding Course of Tuberculosis in Children. H. Wissler.—p. 831.
Criticism of "Chemotherapeutic Tamponade of Pulmonary Cavities.". W. Rubin.—p. 836.
*Transplacental Passage of Penicillin in Course of Pregnancy. E. Grasset, H. de Watteville and P. Dossena.—p. 841.

Tuberculous Bronchial Lesions in Children.—Wissler reports nine children between the ages of 7 and 15 years with tuberculous bronchial lymph nodes. Compression of an intact bronchus, bulging of an eroded bronchial wall or rupture of a tuberculous bronchial lymph node into the bronchial lumen can cause disturbances of ventilation in the corresponding area of the lung. Bronchoscopy revealed that rupture of a bronchial lymph node occurs relatively frequently. Symptoms vary considerably, or there may be complete absence of symptoms. Lobar or segmental shadows corresponding to the area of involvement of the bronchus are important indications These shadows may be explained by bronchial occlusion, but may also be due to aspiration of infectious material. They are occasionally seen where bronchial occlusion cannot be demonstrated. Aspiration of infectious material from a ruptured lymph node may cause formation of infiltrates of various type, which play a part in the pathogenesis of progressive pulmonary tuberculosis. Bronchiectasis frequently results from rupture of a tuberculous bronchial lymph node into the bronchial lumen. It has not been established whether this condition may subside or may lead to a chronic condition and fibrosis of the lung.

Transplacental Passage of Penicillin in Pregnancy.—Grasset and co-workers administered 300,000 units of crystallized penicillin G by intra-muscular route to 15 pregnant women. Duration of the pregnancy varied from six weeks to full term. Delivery of the fetus by cesarean section was performed in six instances, while pregnancy was interrupted by an abdominal hysterotomy for various conditions in nine instances. Consequently, the exact interval between the penicillin injection and the removal of the fetus could be determined. It varied from 30 minutes to two hours. Determination of the penicillin concentration in the maternal and fetal circulation, in the fetal organs and in the amniotic fluid showed that transplacental passage of penicillin was limited in all instances. The penicillin concentration in the fetus was nevertheless sufficiently high to insure an effective antibiotic action against various microorganisms sensitive to penicillin, particularly on the Treponema pallidum. These results confirmed those obtained by the authors in experiments on rabbits and guinea pigs and those obtained by other investigators on the permeability of the placental barrier to penicillin. The permeability does not vary much from two months to full term of gestation; effective antisyphilitic treatment, therefore, may be instituted at any stage of pregnancy. Concentration of penicillin in the maternal blood should be fairly high to insure a minimum spirocheticidal level in the embryo and to prevent the development of penicillin resistance in the Treponema pallidum resulting from too small doses of the antibiotic.

Clinical, Biologic and Histological Study of Fatty Infiltration of Liver in 82 Persons Addicted to Alcohol. R. Cachera, M. Lamotte and S. Lamotte-Barrillon.—p. 3497.
*Course of Fatty Infiltration of Liver in Alcoholics Followed Up by Repeated Puncture-Biopsies. R. Cachera, M. Lamotte and S. Lamotte-Barrillon.—p. 3515.

Fatty Infiltration of Liver in Alcoholics.—Cachera and co-workers report 40 alcoholics, 30 of whom had fatty infiltration of liver in the absence of clinical signs of cirrhosis, while 10 had cirrhosis of the liver. The patients were followed up for six months to two years, during which time they were subjected to liver puncture two to six times. Results of liver biopsy compared with those of clinical examination and liver function tests showed that the course of fatty infiltration in alcoholics is extremely variable. Deposits of fat may persist in the liver for prolonged periods up to two years and may be well tolerated. The size of the liver remained unchanged in 11 patients. Liver function tests remained practically normal. The majority of these patients did not gain weight. Alcoholic intoxication continued. Fatty infiltration was reversible in 13 patients. The excessive fat deposits regressed in the course of several months but did not disappear completely in eight of the patients, while massive fatty infiltration disappeared completely in five patients within one to three months. Microscopic examination showed that the disappearance of the fatty infiltration may be accompanied by repair of the parenchyma. Palpation revealed diminution in the size of the liver. Withdrawal of alcohol, adequate dietary regimen and administration of lipotropic agents, such as methionine, choline and inositol favor the patient's recovery. Repeated puncture-biopsies showed that fatty infiltration may persist for years without inducing much cirrhosis and that fat deposits may be associated with focal or annual cirrhosis. There were other cases in which proliferation of new connective tissue rich in cells occurred in the course of massive fatty infiltration, but the cirrhosis had a progressive course while fatty infiltration disappeared. Puncture biopsy of the liver makes it possible to demonstrate the fat deposits, collagenization, inflammatory attacks and cellular lesions. These observations showed the complexity of lesions that may lead to cirrhosis.

*Blockage of Sympathicus Trunk in Treatment of Inert Pulmonary Cavities. S. Witte.—p. 518.
*Treatment of Traumatic Tuberculosis of Fasciae of Thoracic Wall: Question of Muscle Tuberculosis. G. Hensel.—p. 522.
Technic of Opening Pulmonary Cavities. W. Junge.—p. 530.

Blockage of Sympathetic in Tuberculous Cavities.—Witte discusses tuberculous cavities that do not close despite adequate pneumothorax therapy. For blockage of the thoracic portion of the truncus sympathicus, the author injected 5 cc. of a 2 per cent solution of procaine hydrochloride (novocain®) at the level of the third to the fourth rib three times a week. These injections were given for 55 days. Roentgenologic control examination revealed that the cavity had become smaller after 16 days and was no longer detectable after 37 days. Thus, a cavity that was refractory to various types of treatment for a period of eight months disappeared within six weeks in response to blockage of the thoracic sympathetic trunk. Three other cases are cited in which tuberculous cavities with stiff walls responded to blockage of the thoracic sympathetic trunk. The technic of the injection and the sympathetic innervation of the lung are discussed. A favorable influence is exerted by the predominance of the parasympathetic as a result of the exclusion of the antagonistic impulses from the sympathetic.

Fascia or Muscle Tuberculosis.—Hensel believes that lesions referred to in the literature as muscle tuberculosis were in reality tuberculous lesions of the fasciae surrounding the muscles. The contractile tissues of muscles rarely show tuberculous lesions, so that one may speak of an "immunity" of muscles to tuberculosis. The author observed seven cases of tuberculosis of the thoracic wall. All these patients originally had a pleural empyema. Despite careful rinsing with procaine hydrochloride or with paraaminosalicylic acid, tubercle bacilli *must have been carried into the thoracic wall.* About two weeks after thoracentesis a dense tumor appeared. Softening and abscess formation in the center of this tumor, with formation of a fistula, were observed later. After the empyema was cured, the fistula was extirpated and the muscles and fasciae were sutured in layers. Examination of the specimen disclosed fascial and not muscle tuberculosis.

*Investigations on Penicillin Preparations and Dosage. II. K A. Jensen, P. J. Dragsted and I Kiaer.—p 1075.
*Effect of Single Daily Dose of Dipenicillin in Acute Otitis Media with Special Regard to Bacteriology. J. C. Nielsen—p 1080.
Terramycin. A. Perdrup—p. 1089.

Penicillin Preparations and Dosage.—Jensen and his associates state that the penicillin concentration is much lower in the organs than in the blood, higher in acute and subacute foci of infection than in the organs, but lower than in the blood, and in more chronic foci of infection are so low that general administration of penicillin is seldom curative. According to Eagle, the high penicillin concentration in the blood after administration of penicillin sodium G is wasted because the rate of destruction *of the bacteria does not increase proportionally with the penicillin concentration.* However, bacteria are not found only in the blood, and it is necessary to determine what preparation gives the highest concentration in the organs and in inflammatory processes Experimental investigations indicate that injection of penicillin sodium G and dipenicillin (a mixture of *penicillin sodium G and penicillin procaine G*), which give a high concentration in the blood, can bring about over a short period a higher concentration in the inflammatory processes than that attained by injection of penicillin procaine G. Investigations in man show that this rule holds at least in the treatment of pulmonary diseases. Injection of 600,000 units of penicillin procaine G rarely gives measurable amounts of penicillin in the sputum, but 600,000 units of dipenicillin gives it in almost all cases, and penicillin sodium G is superior to both in this field. The penicillin preparation A, with special affinity for lung tissue, is particularly suitable for treatment of lung infections in which a high penicillin concentration is desired, also in chronic focal processes in the lungs. The development of this preparation paves the way for the production of other preparations with high affinity for the lungs. Chemotherapy must be guided not only by the localization and nature of the infection but also by determinations of resistance. When bacteria that are power*ful producers of penicillinase destroy the effect of penicillin, an* attempt must be made to eradicate them with other agents before penicillin is used again.

Dipenicillin in Acute Otitis Media.—Nielsen gives detailed tabulation of 650 bacteriologic examinations and about 200 determinations of resistance in 65 cases of acute otitis media treated with one daily dose of dipenicillin (a mixture of penicillin sodium G and penicillin procaine G). Patients under 7 years of age were given 200,000 units, those over 7 years, 400,000 units. Dipenicillin is considered preferable to preparations containing only penicillin procaine G, as the penicillin sodium content gives such a high concentration in the blood that the tissue concentration reaches a rather high level. The treatment was continued for one or two days after the discharge ceased and was always applied for at least six days. Of the bacteria of primary importance, *hemolytic streptococci were established in 20 cases, pneu*mococci in 37 and Pfeiffer's bacilli in six. The otitis was due to secondary bacteria, Staphylococcus aureus and Streptococcus faecium, in only two cases. The average number of days before disappearance of the primary bacteria and of duration of the discharge was 3.2 and 5.4, respectively, in the cases with hemolytic streptococci, 2 and 5.3 in the cases with pneumococci and four and six in the cases with Pfeiffer's bacilli. There were no complications. Recurrence was seen *in one case, reinfection in* two. All hemolytic streptococci are sensitive to penicillin; pneumococci are about equally sensitive, and Pfeiffer's bacilli are most often resistant to penicillin but benign in the middle ear. Therefore, about 90 per cent of the cases of acute otitis are cured by penicillin. If six or seven days' penicillin treatment is without effect, the cause should be sought in bacteria resistant or weakly sensitive to penicillin and determinations of resistance made, or possibly streptomycin or aureomycin therapy should be tried.

*Acidity and Ulcer. Studies of Ulcerous Stomach with p_H Stomach Tube H. Kreitner.—p 422.
Hemorrhagic States. K. von Bujniewicz.—p 427.

Acidity and Ulcer.—Kreitner determined the acidity of the gastric juice of 40 patients with duodenal ulcer and of 20 patients with gastric ulcer, by using a p_H stomach tube. This tube facilitated the continuous determination and control of the hydrogen ion concentration in the stomach of the patients and thus helped to produce a kinetic picture of the secretory power of the stomach, at least with respect to the secretion of free hydrochloric acid. Results revealed a primary disturbance of the gastric secretion This disturbance does not consist in the production of a particularly active gastric juice, as some investigators have asserted nor in a specific hyperexcitability of the stomach, with excessive secretion of hydrochloric acid, as was considered by others. The disturbance consists rather in the *continuous secretion of a gastric juice which by its p_H is close* to the optimum of the pepsin effect. The stomach with an ulcerative lesion is regulated in conformity with a p_H value of around 2 This acidity level is maintained also during the interdigestive phase and during sleep. This regulation anomaly is the expression of a sympathetic nervous disturbance. The disturbance may have its origin *in the intramural* nervous terminal plexus of the stomach wall itself at one time and in the spinal cord, *in the medulla oblongata, in the diencephalon or* hypothalamus at another time.

Zeitschrift für Kinderheilkunde, Heidelberg

Hemolytic Crises in Infants with Familial Icterus. E. Grundler.—p 297
*Penicillin Therapy in Scarlet Fever with Particular Consideration of Persistence of Infectivity and Immunity. H. Jebens—p. 303.
Differential Diagnosis of Boeck's Sarcoid K Knuth—p. 318.
Encephalomyocarditis and Its Differentiation from Poliomyelitis F Koch—p 328.
Diphtheria· Epidemiology, Particularly of the Toxic Form H. Niggemeyer—p 368.
Brachymesophalangia of the Little Finger. F. Schmid and F. Junker—p 399.

Penicillin Therapy in Scarlet Fever.—Jebens collected observations on 161 scarlet fever patients; 80 of these were treated with penicillin, *while 81* in alternate order were *not* The dosage was adjusted to the duration of the fever. The administration of penicillin was usually continued for four to five days after the fever had subsided, but treatment was never *discontinued before the end of the sixth day. Defervescence* usually took place within two and one half days (in the control cases in five and one fourth days). The daily dose was usually 160,000 Oxford units, given in divided doses every three hours The total dose was usually around 1,000,000 Oxford units Bacteriologic tests revealed that all children treated with penicillin were free from hemolytic streptococci after three days. In 30, hemolytic streptococci reappeared before the patient was discharged; 18 of these 30 remained in the isolation ward for six weeks, and complications developed in 10 of them The 30 caused a total of six new infections after their return home; *four of these were caused by the 12 who had been* discharged early and two by the 18 who had been in isolation for six weeks. Of the 50 children who showed no recurrence of hemolytic streptococci, seven remained in isolation for six weeks and 43 were discharged early. None of these 50 caused new infections in other persons, although there was a recurrence of hemolytic streptococci after discharge in eight of the 43 Tests investigating the formation of immune bodies between the twentieth *and fortieth days* disclosed that antibody formation was weaker in those in whom treatment was begun early and stronger in those who had had complications and in whom treatment was begun later.

BOOK NOTICES

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Studies in Lobotomy. Milton Greenblatt, M.D., Robert Arnot, M.D., and Harry C. Solomon, M.D., editors. Cloth. $10. Pp. 495, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1950.

This book is a careful scientific evaluation of prefrontal lobotomy in an extensive series of cases at the Boston Psychopathic Hospital. The 500 patients were not only specifically selected on the basis of three to five years' hospitalization, but were also subjected to intensive clinical, anatomic, psychological and sociologic investigations preoperatively and postoperatively, by 30 different contributors comprising all the specialties related to neurology, neuropsychiatry and neurological surgery. The majority of the cases represented long-standing cases of schizophrenia with little probability of recovery by any other means of psychiatric treatment. It was concluded that through prefrontal lobotomy by the "open" method, approximately 40 per cent are benefited, in that they can live outside the hospital, and 20 per cent can be relatively self sufficient and self supporting. A high proportion of the remaining 60 per cent live a more satisfying and contented life in institutions.

A readable review of the recent literature in psychosurgery emphasizes the value of the "open" operation by the Lyerly-Poppen technic, because of the possibility of direct visualization and strict attention to the inferior or orbital frontal fibers which connect the frontal lobes with the thalamus and hypothalamus. With this technic, hemorrhage can be more carefully avoided and localization of the plane of section in relation to cerebral structures can be more accurate. The results in the affective psychoses (involutional and manic-depressive) have been the most encouraging. Lobotomy has also been successfully employed in selected cases of intractable pain, such as with metastatic tumors, phantom limb, tabes and facial neuralgia. Anatomic studies showed a surprising variability of lesions produced by leucotomy dependent on the plane of insertion of the leucotome, the extent of the incision and the adjacent associated hemorrhages and necroses.

The chapter on the technic and complications of the standard prefrontal lobotomy by Dr. Poppen will interest all neurosurgeons who have a justifiable aversion to the "blind" division of brain tissue. The mortality rate was 1 per cent. The postoperative behavior is discussed by Dr. Rose, who notes the temporary disturbance in control of the urinary bladder, the variable period of lethargy with short attention span and poverty of mental content and the excessive reactivity to painful stimuli applied to the skin. The follow-up studies were intensively and elaborately performed and were aimed at discovering which clinical syndromes were benefited and which were not; which individual signs and symptoms were benefited and which were not; what changes following lobotomy were observed in the patient's adjustment within himself, with his family, the community and his work; and what factors were of value in selecting cases which might benefit from frontal lobotomy. Unfortunately, neither preoperative nor postoperative pneumoencephalograms were studied to aid in the determinations of preoperative pathology, as distinguished from postoperative pathology and secondary degenerations. However, electroencephalograms and electrocortical stimulation studies were undertaken. The anatomic studies on the six patients who died from 11 to 235 days postoperatively emphasized local and distant neuronal loss in addition to the destruction anticipated, as a consequence of the planned resection of the cortex and the anatomic severance of the frontal white fibers. This was dependent not only on the site and method of section but also on the circumstances of hemorrhage as the section is carried through its planned extent, and the methods used to control hemorrhage. For example, severance by the method of suction tended to cause more damage from greater tissue loss and concomitant thromboses than the method of blunt section by a leucotome. Regardless of whatever external cerebral reference points the surgeon may utilize, the location and orientation of the incision in the cerebral substance are subject to variations in all three planes of space occupied by the frontal lobes, and, finally, the operator himself becomes the most variable factor determining the lateromesial extent, depth and width of the severance of cerebral tissue. Hence, the attempt to correlate the behavioral changes with specific topographic areas in the frontal lobe and anterior thalamus must also take into account concomitant damage to the cingulate gyrus, fibers of the anterior limb of the internal capsule and the subthalamic region and the island of Reil. These changes probably account for the great variations occurring clinically in postlobotomy patients. The relative values of topectomy, thalamotomy and cortical undercutting were also considered. On the whole, this book presents an unbiased and objective outlook on the assets and liabilities of lobotomy—the degree of benefits to be expected as well as the defects which may result.

Malignant Disease and Its Treatment by Radium. Volume III. By Sir Stanford Cade, K.B.E., C.B., F.R.C.S., Surgeon, Westminster Hospital, London. With a Foreword by Sir Ernest Rock Carling, F.R.C.P., F.R.C.S., F.F.R., Consulting Surgeon and Vice-President, Westminster Hospital, London. Second edition. Cloth. $12.50. Pp. 446, with 548 illustrations. The Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1950.

This is the third volume of a four volume series and deals with common neoplasms of the breast, thorax, abdomen, pelvis and the male and female external genitalia. It continues the authoritative presentation of the incidence, symptomatology and diagnosis of malignant disease characterizing the previous volumes. Although chiefly concerned with radium therapy, the book contains adequate discussions of the most appropriate methods of treatment. The illustrations are numerous, and some are excellent, but those of lung neoplasms are poorly reproduced. The radiotherapy described represents one English view, which may be at variance with the American trend toward more extensive employment of roentgen therapy. The volume should be useful to clinicians dealing with the diagnosis and treatment of malignant disease, regardless of the emphasis on radiation therapeutics.

Supervoltage Roentgentherapy. By Franz Buschke, M.D., Simeon T. Cantril, M.D., and Herbert M. Parker, M.Sc. Cloth. $10.50. Pp. 297, with 150 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This book is a valuable, detailed, well written and amply illustrated record of work done with an x-ray machine delivering roentgen rays with energies from 200 to 800 kv. The results in carcinoma of the esophagus, the maxillary sinus, the larynx, the urinary bladder, the breast and the cervix uteri, in malignant tumors of the pharynx and in pituitary adenoma are described. Of special interest are the favorable results in otherwise inaccessible esophageal tumors and the technical hints gathered from the work with the hypophysial tumors. Of interest also are the reasons given by the authors (page 200) for omitting postoperative radiation after a carefully done radical operation for carcinoma of the breast, and, finally, their general conclusion that promise of future advances lies not so much in exploring the region of higher voltages as in that close cooperation whereby the treatment is adapted as precisely as possible to the particular case. The book is recommended to the attention of both surgeons and roentgenologists.

Les maladies des coronaires: L'infarctus du myocarde, l'insuffisance coronarienne. Par Ch. Laubry, professeur de Clinique cardiologique à la Faculté de médecine de Paris, et P. Soulié, professeur agrégé à la Faculté de médecine de Paris. Second edition. Paper. 2400 francs. Pp. 618, with 299 illustrations. Masson & Cie, 120, Boulevard Saint-Germain, Paris 6^{e}, 1950.

The first edition of this extensive monograph appeared during the German occupation in 1943, while France was cut off from England and America, and it is fitting that this edition should appear in the year of the First International Cardiological Congress, of which Professor Laubry was the distinguished president. The authors have now "had the full echo of the revolutions in electrocardiographic technic operating in America."

The subject matter is well covered. There are sections on the anatomy, physiology and pharmacology of normal coronary vessels. There is a chapter on etiology. That on the abnormalities of the electrocardiogram comprises 68 pages. The chapter concerned with the clinical description of acute coronary thrombosis is 114 pages long and is done with great clarity and order, although the value of such a detailed exposition is doubtful. Pathological anatomy and the physiological and pharmacodynamic changes induced by coronary disease are also discussed at length. The authors' views on therapy differ but little from those most current in the United States. However, they favor respiratory exercises in the treatment of the patient with angina and are not averse to such agents as baths and massage. In acute cardiac infarction they have had unhappy experience with bishydroxycoumarin (dicumarol®) and regard it as dangerous. They are inclined against the use of high concentrations of oxygen.

The book is profusely illustrated with reproductions of electrocardiograms, of diagrams showing their relation to cardiac lesions, of roentgenograms, photomicrograms and gross specimens. The reproductions of the first two are excellent, but some of those of roentgenograms and microscopic sections are only fair, while those of gross specimens leave much to be desired. The scope of the work is evident from the bibliography, which occupies 47 pages and gives over 1,000 titles, many of them by American authors. Far too detailed to be put into the hand of medical students, this extensive monograph will be of value to experts in the field as a critical compilation of the literature and as a record of the impact made by the more experimental American school on a great medical tradition which has remained for a long time in the descriptive phase.

Annual Review of Physiology. Victor E. Hall, Editor, Jefferson M. Crismon and Arthur C. Giese, Associate Editors. Volume XII. Cloth. $6. Pp. 609. Annual Reviews, Inc., and the American Physiological Society, Stanford, Calif., 1950.

Each of these annual reviews as it appears affords the medical reader a priceless opportunity to note the present status of some of the perennial problems of physiology and to discover new trends in research. The present volume lives up to its predecessors in these respects, and in addition contains a prefatory chapter by DuBois, Fifty Years of Physiology in America, which brings out interesting contrasts between 1900 and 1950 as regards the life of the physiological investigator. As examples of the perennial problems referred to might be mentioned the effects of cold, the existence of gastrin and the multifarious aspects of coagulation. The cause of hypothermic death is still in doubt (page 123), and the proof that gastrin exists is weak (page 209). The proposal of a new theory of coagulation (page 239) will be hailed with groans by medical students, whose minds in the past have certainly been overburdened with mistaken and impractical information on the subject. In view of the importance of hemorrhage and thrombosis, much interest attaches to recent work, referred to in this volume, on substances hastening and retarding coagulation.

In the field of respiration, the war prompted much excellent work on anoxia, decompression phenomena and oxygen intoxication. The physiological world has recovered from its phobia of resuscitation apparatus and its obsession with the virtues of carbon dioxide, two favorite notions of the late Yandell Henderson; it is now agreed that "mechanical respirators . . . improve the chances of survival" (page 191) and that the "addition of carbon dioxide was of no value" under certain conditions (ibid.). New trends are exemplified by the introduction of electrophrenic respiration (page 191); the development of cybernetics and the study of the wiring of the brain, whereby tinnitus, for instance, is revealed as a feedback phenomenon (page 422); continued disclosures of the treacherous nature of ionizing radiations (page 29); further probing into the submicroscopic structure of cells, and the demonstration of the particulate nature of such things as the "killer character" in paramecia (page 63).

The stimulating effect of practical industrial problems on research is exemplified impressively by recent discoveries regarding artificial insemination (page 537). Because of their exceptional potentialities, spermatozoa are very informative cells for experimentation. Large scale studies were necessitated by the fact that in a single year "2.5 million cows have been inseminated in the U. S. A. alone, and the enterprise which provides the semen and performs the inseminations is now a 12 million dollar industry employing more than 2,000 men and women full time." The resulting harvest of scientific information has been of the greatest practical and theoretical interest. This volume is recommended to the attention of everyone working in the medical sciences, particularly to authors anxious to make sure of the completeness of their information on a given subject.

Russian Impact on Art. By Mikhail Alpatov. Edited and with a Preface by Martin L. Wolf. Translated from the Russian by Ivy Litvinov. Cloth. $7.50. Pp. 352, with 32 plates. The Philosophical Library, Inc., 15 E. 40th St., New York 16, 1950.

The author of the book is a professor at Moscow University and a recognized expert on the history of art. The book was translated from Russian into English by Ivy Litvinov, the English-born and English-educated wife of the well known statesman. The title suggests that the author is about to discuss the subject of Russian art per se, without necessarily attempting to prove its superiority over the art of the rest of Europe. He makes an attempt to be objective but is eventually carried away by the temptation to demonstrate that the Russian art is somehow more "original" and more "profound" than the art of Western Europe because it is closer to the soil. This is a familiar theme which runs through all the recent works emanating from the U.S.S.R., whether their authors discuss discoveries in the field of science or accomplishments in the field of arts. This movement, sponsored by the authorities, is intended to replace "the slavish adoration" by the Russians of Western Europe, its culture and all it stands for, by insisting on the superiority of things Russian. In this it differs little, if at all, from the reactionary slavophile movement of the Tsarist regime.

The complaint that Western Europe, by which is meant Germany, France and England, failed to comprehend and to appraise the Russian art is of course not true. Thus, Nietzsche early spoke of Dostoevski in terms of highest praise. More books and interpretations of that author appeared in the German than in the Russian. Mérimée and Voguet introduced the Russian classics to the French public. The popularity of Tolstoy, Dostoevski and Turgenev with the French, the Germans, the English and the Americans requires no comment. Were the author to stress that the Russian prose fiction, as represented by the famous triad, was superior to that of the prose of Western Europe, no one would challenge his statement. But, in the fields of architecture, sculpture and painting, Russian art, when compared with that of the Italian Renaissance, the Flemish school of painting and the French painting of a later period, is totally insignificant. Most of the famous churches and palaces of the Tsarist Russia were designed by Italian architects. The famous Rastrelli, whom the author claims for a Russian, was born in Italy and had his artistic training in that country. Almost all Russia's talented architects, painters and sculptors studied in Italy and in France. The author fails to acknowledge the indebtedness of his country to Western Europe in the matter of fine arts. His partiality to things Russian is evident in such statements as that Lomonosov, like Leonardo da Vinci and Bacon, is one of the last "encyclopedic geniuses" of Europe, that Tchaikovsky is more profound that Wagner, that Chekhov's short stories are superior to those of de Maupassant, that Derzhavin was a great poet and that the essayist Chernyshevski understood life "more fully, deeply and broadly" than Hegel, the great German philosopher and esthetician. Not satisfied with his own prejudices, the author invokes those of the older Russians. He quotes Tolstoy, who, after his conversion to Christianity, decided that French literature was immoral, the painter Kramskoy, who considered French painting "unprincipled," and Moussorgsky, who thought that the German symphonic music was too abstract and so dubbed it "mathematics." All these statements reflect nothing more than exaggerated nationalism, a malady which was well known and was vigorously resisted by the enlightened Russians of the type of Turgenev, Belinsky, Herzen and others.

There is no denying that Russia had and has its own art and its own artists and that like the art of any other country these works possess a certain originality which is distinctly theirs. The author attempts to cover entirely too vast a field. As a result, most of the chapters, with the exception of those dealing with the art of icon painting, are inadequate and superficial.

Preventive and Corrective Physical Education. By George T. Stafford, Ed.D., Professor of Physical Education, University of Illinois, Urbana, Ill. Second edition. Cloth. $3.75. Pp. 312, with 74 illustrations by Gene A. Logan. A. S. Barnes and Company, 101 Fifth Ave., New York 3, 1950.

This book for the physical education teacher stresses the importance of a schedule of corrective work in physical education consistent with the interests and capacities of those students unable to profit from the regular program of activities. In many schools too little is done to provide suitably graduated exercise for the handicapped child or the pupil with minor deviations from the normal. A program of therapeutic exercise to be administered under medical direction by the physical education teacher is recommended for this group. A practical plan for such a program includes (*a*) a broad activity program for students found by medical examination to be physiologically sound, (*b*) group corrective work for those with minor health problems, such as poor posture or weak feet, (*c*) individual corrective work on medical prescription for those with more serious disorders, and (*d*) supervised rest on medical advice for certain children during the physical education period.

The author emphasizes the need for developing this kind of program at the elementary school level when the best results may be expected. Since in the corrective aspects of physical education the teacher is actually a technician carrying out a medical prescription, a major portion of the text is devoted to developing a basic understanding of the varying conditions with which he may be expected to deal, a working terminology, the applicable exercises and the kinesiology involved. The volume should be useful as a textbook for prospective physical education teachers and as a guide for those in service. It is to be hoped that its emphasis on corrective exercise for a group of students who have often been neglected will stimulate the development of more comprehensive physical education programs designed to meet the needs of all students.

The Cerebral Circulation in Health and Disease. By Carl F. Schmidt, A.B., M.D. Publication Number 68, American Lecture Series, A Monograph in American Lectures in *Physiology*. Edited by Robert F. Pitts, M.D., Ph.D., Professor of Physiology, Syracuse University School of Medicine, Syracuse, N. Y. Cloth. $2. Pp. 78, with 12 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This is a valuable addition to the physiological and clinical literature on cerebral circulation. After a brief description of the arterial and venous cerebral system, in which the results of cerebral angiography are emphasized, the physiology and pharmacology of cerebral circulation are discussed. These investigations are largely based on the measurement of the diameter of the pial vessels and temperature changes in various parts of the brain. Since definite species differences exist in the reactivity of the cerebral vessels to physiological factors and to drugs, the development by Kety and Schmidt of a quantitative method for the determination of cerebral circulation which is applicable to man was of greatest importance. The results obtained with this method in several clinical conditions are described. This little book is highly recommended to physiologists and clinicians. The bibliography is rather incomplete.

Recent Advances in Chemotherapy. Volume I. By G. M. Findlay, C.B.E., Sc.D., M.D. Third edition. Cloth. $7.50. Pp. 625. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St., Philadelphia 5, 1950.

When the first edition of this work was published 20 years ago, chemotherapy, with the exception of antisyphilitic therapy, was confined largely to tropical diseases. Since then, the discovery of the sulfonamides and the antibiotics has removed this subject from the realm of the esoteric to a place of major importance in therapeutics. As evidence of the increased scope of chemotherapy, it may be noted that the first edition of this work occupied a single volume; the present edition, when completed, will encompass four. This volume may be considered as a revision of earlier ones, since it is confined to the chemotherapy of protozoan diseases, the majority of which are tropical in origin. The diseases discussed are those due to insects (principally scabies), to helminthic infestations (amebiasis, leishmaniasis, trypanosomiasis) and to various protozoa (babesiasis, bartonellosis, toxoplasmosis, coccidiosis and trichomoniasis).

The pharmacology of the agents discussed is adequately reviewed, and the principles and details of therapy are presented. The only major criticism that might be leveled at this work concerns the lack of adequate discussion of the pathogenesis of the diseases for which therapy is recommended. A more complete outline of the life cycles of some of the organisms and a discussion of the routes of the infection and its natural course would aid the reader in understanding the principles and advantages of the various forms of therapy and in utilizing the text adequately. It is interesting to note that considerable attention is paid to veterinary chemotherapy, particularly in the chapter on helminthic infections, where an excellent discussion of the use of phenothiazine is given, and in the chapter on miscellaneous protozoal infestations, where such subjects as blackhead of turkeys and fowl coccidiosis are adequately treated. This volume should be of value to students of tropical medicine, those interested in therapeutics and veterinarians.

Aetios of Amida: The Gynaecology and Obstetrics of the VIth Century, A. D. Translated from the Latin edition of Cornarius, 1542, and fully annotated by James V. Ricci, A.B., M.D., Clinical Professor of Gynecology and Obstetrics, New York Medical College, New York. Cloth. $7. Pp. 215. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St., Philadelphia 5, 1950.

Dr. Ricci, in this scholarly translation of a sixth century encyclopedia of obstetrics and gynecology, has made available to his fellow practitioners a classic of great worth. In the accumulation of a knowledge which will qualify one today in the practice of medicine, too often the physician's gown hides abysmal ignorance of the roots of the healing art, and the centuries of groping which have culminated in the precision methods of 1950 could be no better emphasized than by perusing this small volume.

It must be reiterated that Aetios' work was encyclopedic; in the manner of a learned student, he condensed and edited the medical knowledge of the first five centuries of the Christian era. Dr. Ricci now places this at the reader's elbow for his moments of leisure. No one can fully appreciate the arduous task involved in this translation and the accompanying 96 pages of notes, definitions and other clarifying addenda, which are all so skilfully handled by a busy physician. There is scarcely a dull line in the book. The dissertations are numerous, and each the literary product of an "authority," displaying a knowledge which seems at times unbelievably keen and at the same time naïvely humorous. Excerpts from two topics are cited as typical: Archigenes and Leonides, prior to 200 A. D., gave an excellent description of the physical signs of cancer of the breast. "Further, it produces piercing pains radiating over a wide area, so that often it excites by sympathy a malignant inflammation of the axillary glands. . . . Indeed ulcerated cancer erodes continuously and penetrates to the very depths, for it cannot remain stationary, and it discharges a sero-sanguineous matter worse than the poison of wild animals; detestable in amount and odor. . . . Cancers arising in the breast invariably must be abandoned, . . . incurable, because they cannot be extirpated completely. . . . But those tumors which develop on the top of the nipple are curable because the diseased part can be easily excised." In treatment, Leonides states, "I make the patient lie down." Then progressive excision and cauterization was done, followed by dressings to promote suppuration. During healing, "The patient must abstain from wine, indigestible foods, and cold drinks." Before surgical intervention, "Of the more simple remedies let her drink the warm blood of a freshly killed goose or duck. . . . Of value also is a decoction of crayfish kept in asses' milk for five days." The latter, if used for 35 days, "will render cancer of the breast very amenable." These remedies one should "use with confidence and disregard the scoffers who but little understand the nature of the disease."

Amenorrhea, then as now, was no trivial symptom: "For the sake of conception, and because almost all women live with that purpose, monthly periods are necessary." The complications which might ensue varied from insanity to erysipelas. The common causes of this symptom are listed, but Rufus and Aphasia naïvely add that "singers and dancers naturally do not menstruate, because in these there is nothing left (for menstruation), since excessively violent exercise consumes it." The choice of remedies was as varied as it is today, but all others failing, these early endocrinologists found most successful a laxative of gummy thistle and parsley (estrogen withdrawal?).

This is not a desk reference volume for the busy practitioner; it contains not a single line of commercial value. Its appeal, however, should be universal to physicians of today who are directly, or only remotely, interested in the diseases of women. Structurally, although there are no illustrations, the book is excellent.

Einführung in die innere Medizin. Von Dr. Hans Julius Wolf, ausserplanmässiger Professor für innere Medizin an der Universität Göttingen. Fourth edition. Cloth. $6.50. Pp. 653, with 73 illustrations. Georg Thieme, Diemershaldenstrasse 47, Stuttgart O; Imported by Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1949.

This textbook on internal medicine is not so brief as a quiz compend nor so voluminous as a fully detailed textbook, which is sometimes so detailed as to be confusing to medical students. The work is based on the author's experience as a teacher and practitioner and may, as he suggests, be useful in orienting medical students entering their clinical years and also as a quick reference to the essential facts for general practitioners. The fact that only eight years have elapsed between the first and fourth editions betokens the work's popularity. The book has a detailed table of contents covering 14 pages which, in general, is arranged by systems or organs. In addition, there are sections on the infections, contagious and noncontagious, on the animal parasites of man and on the common chemical poisons. The space devoted to the discussion of each disease varies with the author's estimation of its importance. In general, the clinical picture, physical observations, diagnosis, etiology, course and treatment are all briefly summarized. Where complications are common they are discussed, as is the pathological anatomy and physiology and the significance of technical aids in diagnosis where these are of sufficient importance. Although many of the discussions are brief, they are clear and readily grasped. Since discussion of conflicting theories and points of view is avoided, the presentation appears somewhat dogmatic, but this is doubtless unavoidable because of the nature of the work.

The book is attractively bound in cloth, clearly printed on good quality paper, and the illustrations, mainly in black and white, are satisfactory. The reproductions of roentgenograms are particularly good and well chosen. There are a few colored plates, mainly of blood smears, and some useful charts. There is a good index but no bibliography. The writer has a good knowledge of the literature and a clear style. The emphasis placed on different diseases naturally varies somewhat from that usually found in comparable American works, mainly because some diseases common in the western hemisphere are absent or rare in Europe. Not that exotic diseases are neglected, for there is a special section covering them. Certain things are omitted, such as some of the rarer conditions like Löffler's syndrome and Reiter's disease and marihuana addiction, but these omissions do not detract from the adequacy of the book as a whole.

Exercices chirurgicaux (de l'amphithéâtre à la salle d'opérations). Par J. Sarroste et R. Carillon. Avec la collaboration de Pesme, et al. Préface due Médecin-Général Paitre. Second edition. Paper. 2100 francs. Pp. 441, with 350 illustrations by Berkman, Souday and Bonde. Librairie Maloine, 27, Rue de L'École-de-Médecine, Paris 6e, 1950.

This work on surgical technic is well organized. Throughout the book, for all subjects discussed, a brief introductory statement is followed by definitions, indications, anatomic background and surgical technic.

The book begins with a description of ligature of the arteries, after which, in the second chapter, exposure of the peripheral nerves is discussed. This is followed by a section written in collaboration with M. E. Sarlin on surgery of the lumbar sympathetic nerves. The third division of the book concerns surgery of the bones and articulations (amputations, disarticulations, resections and arthrodeses). This portion is a thorough, succinct evaluation of the principal operative procedures in this domain. In the fourth chapter, operations on the head, neck and spinal cord are described. Here also the original orderly scheme is followed. Regrettably, the material on surgical treatment of the spinal column is abbreviated. A discussion of ophthalmic surgery is added here. In the chapter on surgery of the thorax, perhaps it would have been well to describe the emergency approach to the heart, which is so important in cases of sudden cardiac arrest. The description of radical mastectomy is overcondensed. The subject of surgical therapy of the intra-abdominal organs (chapter 6) is introduced with an exposition of surgical procedures for hernia. It is heartening to note that the work of Fontan, a pioneer in gastrostomy and the first to construct a valve, is given due credit. Routine operations on the small and large intestines are well presented. The description of the operation for removal of the rectum in cases of malignant disease could be augmented advantageously with more modern concepts. This applies also to the chapter on surgery of the biliary tract. The closing chapter deals with surgery of the genitourinary apparatus. Here also the descriptions are curtailed. Hysterectomy is described, but other operations on the female genitalia are omitted. The illustrations are clear and, for the most part, diagrammatic. The work will serve its purpose for the student and general surgeon who read French; to them it can be recommended with the reservations noted.

Die Tuberkulose vom Standpunkt des Internisten. Von Prof. Dr. Hans Kutschera-Aichbergen. Paper. $5.70. Pp. 308, with 43 illustrations. Springer-Verlag, Mölkerbastei 5, Wien 1, 1949.

Dr. Kutschera is professor of medicine at the University of Graz, Austria. This book is written primarily for physicians interested in the medical treatment of tuberculosis. It should serve for better training of young physicians in recognition of early cases of tuberculosis in which medical treatment still could be quite successful. Dr. Kutschera has found this training considerably deficient, as is obvious from various histories he cites, in which the correct diagnosis of tuberculosis was made only after the patients had been treated for a prolonged time on the basis of a mistaken diagnosis.

To the American reader it is of particular interest to realize the tremendous increase of tuberculosis in certain parts of central Europe, where the mortality figures increased from four to six times over those in the year preceding the outbreak of the second world war. The death rate is about 500,000 per year among the population of approximately 500,000,000 people in Europe. Dr. Kutschera draws from a broad experience with tuberculosis. In the impoverished countries of central Europe, it is necessary to use comparatively inexpensive methods for routine checking of the large populations. Roentgenography as a diagnostic means is used only if other observations, such as diminished vital capacity, are suggestive of pulmonary disease. Obviously, spirometry is used rather extensively in the hospitals of central Europe.

Of particular interest is the experience of the author with active immunization of otherwise almost hopeless cases of advanced pulmonary tuberculosis with virulent tubercle bacilli, producing superinfections in the skin. These experiments, which in a considerable number of patients were unbelievably successful, are based on the observation that incidentally produced infections of the skin (following tracheotomy in tuberculous patients) have a beneficial effect on the course of severe open cases of pulmonary tuberculosis. Dr. Kutschera believes, that such active infections, either by the same strain recovered from the patient or by a virulent strain from another tuberculous patient, have a curative effect by increasing the resistance of the host against the pulmonary disease. In general, the factor of resistance is much more conspicuously stressed throughout the book than infection, per se.

One might disagree with some decidedly dogmatic statements, by no means proved by sufficiently clarified morphological data: for instance: cases of pulmonary tuberculosis are classified according to two large groups, one as beginning with a unicentral lesion (in particular the various forms of primary filtration, Assmann) the other the multicentric beginning types. While the former is admittedly the effect of an exogenous new infection (and with this statement certainly numerous pathologists will agree), the multicentric form is supposed to be based on hematogenous invasion of both lungs from a still active focus, usually in the lymph nodes of the primary complex. The later pictures in both types are admittedly very similar to each other, especially in the progressive form. There is no sufficient evidence to date to support the view that the bilateral phthisis, progressing from the apical to the basal areas, is the effect of a secondary hematogenous spread to the lungs.

There is no question that this book may be of some value to the practicing physician in central Europe who is confronted with tuberculosis in its very early stages. Because of the book's local character it will be of interest only to the reader who is interested in the problem of tuberculosis from a global standpoint.

A Histology of the Body Tissues with a Consideration of Their Functions. By Margaret Gillison, Lecturer in Physiology at the I. M. Marsh College of Physical Education, Liverpool. Foreword by R. C. Garry, D.Sc., M.B., Ch.B., Regius Professor of Physiology, University of Glasgow. Cloth. $3.50. Pp. 220, with 103 illustrations. The Williams & Wilkins Company, Mt. Royal & Guilford Aves., Baltimore 2, 1950.

This small textbook is written primarily for students of physical therapy and physical education and is meant to bridge the gap between anatomy and physiology. The descriptions of cells and tissues are lucid and easy to follow. The text is well illustrated by drawings which are simplified representations of microscopic sections. The vocabulary is extensive for an elementary text, and some terms are used rather loosely; for example, the author refers to the lining of Bowman's capsule as squamous epithelium.

The scope of the book is limited to an introductory chapter on the anatomy and physiology of a typical animal cell, with the amoeba as prototype, followed by chapters on the preparation of tissues, surface and lining tissues, connective and supporting tissues, cartilage and bone, blood and tissue fluids, muscle tissue and the nerve tissues. The introductory chapter is particularly good, as is the brief description of the preparation of tissues for microscopic study. The histological structure of organs is not included, except briefly in connection with the topics of the various chapters. In general, this is an excellent elementary textbook of histology. This book should be of value to students of physical therapy and physical education and to nurses. It should also be of value as an introduction to animal biology.

The Cytology and Life-History of Bacteria. By K. A. Bisset, Ph.D., Lecturer in Bacteriology, University of Birmingham, Birmingham. Cloth. $3.50. Pp. 136, with 43 illustrations. The Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1950.

This volume is a polemic against confining the study of bacteria solely to their physiological properties. The author considers them as living cells with the same structure and functions as other living cells. The limitations of past and present technics for the study of bacterial morphology are emphasized, and new methods are proposed. These include special staining technics for the demonstration of the various components of the bacterium, including nuclei and chromosomes. Also included are discussions of reproduction, sexuality, life cycles and genetics of bacteria. A minimum of proof of structure is established by the author; the problems remain unsolved. The book will be of interest only to microbiologists, geneticists and cytologists who are interested in cell structure and cell metabolism.

One Hundred Years of Indiana Medicine, 1849-1949. Published in Connection with the Centennial of the Indiana State Medical Association. Dorothy Ritter Russo, Editor-in-Chief. Prepared under the Direction of Charles N. Combs, M.D., and Edgar F. Kiser, M.D. Cloth. $4. Pp. 195, with illustrations. Indiana State Medical Association, 1021 Hume Mansur Building, Indianapolis 4, 1949.

This book is a review of 100 years of medical history in Indiana. Dr. C. N. Combs has accumulated material relating to the Indiana State Medical Association over a period of many, many years, and it must have been no small chore to sift it and finally arrive at a choice for inclusion in the book. The book is, of course, concerned with only one of the 48 states, but it should be of interest to doctors elsewhere, because pioneer times in Indiana typified much of that era in the entire Northwest Territory. From this point of view, the editors and other contributors have done exceedingly well with special phases of Indiana medicine and have produced a literary diorama of medical effort and progress in which they and other American physicians may take pride.

Some of the saltier portions in the section by Dr. Combs on the history of the Indiana State Medical Association might be quoted here:

> 1849. Also at this meeting they grappled with problems that, for the sake of science, we all regret they left undetermined: Resolved, That a Committee be appointed by the president to collect, in a systematized form, facts on the duration of pregnancy, and the causes which influence sex.
>
> 1862. Many state medical societies and even the American Medical Association missed one or more meetings during the Civil War, but Indiana did not fail to keep going. However, the usual May meeting was postponed until November and the attendance was slight. The membership was 300 and the annual expense was $93.00.
>
> 1867. A member was expelled for reading a paper on the progress of medical science when it was discovered to be an exact copy of an address delivered by a New York doctor at the New York State Society meeting the year before.
>
> 1877. Governor Thomas Hendricks (granduncle of our Tom) was thanked for being the first governor of Indiana to recommend a State Board of Health.
>
> 1880. Doctor Beck of Fort Wayne wanted to levy $1.10 per member to be paid to the family of a deceased member as doctors were notoriously poor.
>
> 1888. The 38th annual session will go down in the annals as the most memorable—certainly to that date. For the banquet, James Whitcomb Riley, our own Hoosier poet, wrote the original and apropos verses to each toast, and he responded with the premier reading of his now celebrated poem, "Doc Sifers." Bill Nye could not be there but sent a characteristic telegram, "Sorry I cannot be there. May you and your associates continue to take life easily as heretofore." Concluding the seventeen speeches the meeting "adjourned at three o'clock and four minutes, a. m."
>
> 1890. A whole county society was expelled because the majority of the members were physiomedicals and eclectics.
>
> 1893. There was a case reported of suppurative appendicitis cured by calomel and sweet oil. (It was evident that the abscess ruptured into the bowel thus effecting the cure.)
>
> 1898. . . . This year was notable because it gave the meeting a new scientific feature, the pathological exhibit of 175 specimens.
>
> 1901. A paper on spinal anesthesia lies unheralded and unsung as far as the bibliographer is concerned for its title is "Medullary Narcosis."
>
> 1919. A motion was carried to exclude from membership any physician who sought by changing his location to profit by the patriotism of physicians who went to war.

Marriage and Family Relationships. By Robert Geib Foster. Revised edition. Cloth. $2.75. Pp. 316. The Macmillan Company, 60 Fifth Ave., New York 11, 1950.

This book was first published in 1944. It is a comprehensive presentation of problems arising both in marriage and family relations based on the theory advanced in many of the writings of the Menninger group, which stresses the choice facing human beings between love and hate. "Love leads to constructive acts and accomplishments, whereas hate leads to self—and world—destruction." The usual procedure in books of this kind is followed, proceeding from self analysis and self understanding to a discussion of basic needs and human behavior and the understanding of "friendliness patterns" in relation to marriage. From this logically follows mate selection, looking forward to marriage and the evolution of a satisfactory family life, including the introductory year of marriage, sex, money, home, children and relatives by marriage. The family in relation to society as well as other sociologic and human relations are dealt with. There are extensive references for supplementary reading. The book is given a textbook flavor by questions and exercises related to the chapters. It can be recommended for use at the college level and as supplementary material in the hands of discriminating leaders for group discussions in the advanced teens.

Experiments in Social Process: A Symposium on Social Psychology. Edited by James Grier Miller, Professor of Psychology, Department of Psychology and Division of Psychiatry of the Department of Medicine, University of Chicago. Cloth. $3. Pp. 205, with 7 illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 18, 1950.

To consider current social problems, the technics being developed or refined for their solution and the results of recent experimentation and study in the field of social psychology, experts in various branches of the field were invited to participate in a symposium at the University of Chicago in November 1947. The reports of participants, describing representative samples of recent work and their anticipated application to broader social problems, are presented in the first eight chapters of this book. In the ninth chapter all members of the symposium are joined by a nuclear physicist for a round table discussion of the ways in which the physical and social scientists can best cooperate to remove the threat of mass destruction arising from the development of atomic energy. A relatively young science, social psychology is able to report progress and look forward to even greater advances largely because of improved methodology. The sharpening of such technics as the public opinion survey, field observation and experiment, the laboratory experiment and clinical study, is described and illustrated. The importance of a scientific methodology is emphasized by all the contributors. The exposition and evaluation of this aspect of research in social psychology is one of the chief contributions of the book.

In most instances the writers try to relate or illustrate technic and theory with empirical data from controlled experimentation. Specific experiments with their results are described. There is some tendency, perhaps because of limited space, to fall back on generalizations which seem either premature or unsupported by the discussion and which clutter more than clarify. Most of the contributors, however, seem to be aware of the present shortage and great need of experimental data in a subject which historically has consisted largely of theorizing. Though not highly technical, the book offers considerable insight into the present achievements and future ambitions of the social scientists. The full array of problems to which present technics are applicable has been by no means fully explored. Neither has much experimental data been collected or systematized. But the contributors seem to share the feeling that, although social psychology is in its infancy as a science, it is making a start at forging the solutions to the interpersonal and international problems that beset society.

Certain chapters are exceptionally well written. The subject matter is often entertaining as well as informative. The book, as might be expected from its composition, is not, however, of uniform quality. The material presented is not always new, penetrating or significant. But because of the wide diversity of topics dealt with under one cover, the physician will get a valuable over-all view of this field. The book will add to his awareness of a new sphere of progress which will more and more affect him both as a physician and a citizen.

Old Age: Some Practical Points in Geriatrics and Gerontology. By Trevor H. Howell, M.R.C.P., Lecturer in Problems of Old Age, St. Bartholomew's Hospital, London. Second edition. Boards. Pp. 108, with 9 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London W.C.1, 1950.

In this small volume, Trevor H. Howell has condensed his long experience with clinical problems among older persons and the chronic sick into a readable, useful book. The chapters on Approach to Old Age, Geriatric Rehabilitation, Diseases in Old Age and The A.B.C. of Geriatrics are especially noteworthy for their discussion of the general problems of geriatric medicine. This is not an exhaustive, detailed textbook, but it nevertheless contains many interesting observations on diagnosis, treatment and rehabilitation in respect to diseases commonest among older patients. As the author well says, "Geriatrics is more a state of mind than a branch of medicine or a mode of treatment. It is a reaction against the belief that after sixty a patient is too old to be medically interesting or therapeutically rewarding." The reading of this book will be found rewarding by all physicians who see older patients.

Lippincott's Quick Reference Book for Nurses. By Helen Young, R.N. Editorial Board: Department of Nursing, Faculty of Medicine, Columbia University, Presbyterian Hospital School of Nursing, New York, Mary Elizabeth Allanach, A.M., R.N., Assistant Professor of Nursing, and others. Sixth edition. Cloth. $3. Pp. 626. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St, London, W.C.2; 2083 Guy St., Montreal, 1950.

This book contains up-to-date information. Many changes have been made in this edition, particularly in the section on pharmacology. A table of less commonly encountered diseases has been added, and recent developments in diet therapy have been included. The content is divided into several sections and provides general information on pharmacology, nursing technics, medical and surgical nursing, obstetric nursing and diet therapy. The appendix includes a glossary, tables of measurement, popular and official names of medicinal preparations and diagrams of pressure points showing relation to arteries and bones. This is a handy little volume; if somewhat thinner, it could be called pocket size. The format is pleasing; it is easy to read, and the type and paper are excellent.

Simmonds' Disease: Extreme Insufficiency of the Adenohypophysis. By R. F. Farquharson, M.B., F.R.C.P., Professor of Medicine and Head of the Department, University of Toronto, Toronto. Publication Number 31, American Lecture Series, A Monograph in American Lectures in Endocrinology. Edited by Willard O. Thompson, M.D., Clinical Professor of Medicine, University of Illinois College of Medicine, Chicago. Cloth. $2 Pp. 93, with 5 illustrations. Charles C Thomas, Publisher, 301-327 E Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd, 19 Broad St., Oxford, England; The Ryerson Press, 299 Queen St, W., Toronto 2B, 1950.

This is a valuable monograph. The pathogenesis and pathology are completely and clearly developed. The far reaching effects of this condition on the other endocrine glands and the viscera are discussed in some detail. The clinical course of the disease is thoroughly reviewed. Therapy is given only general discussion, with suggestions for substitution therapy for hypogonadism, hypoadrenalism and hypothyroidism. The advent of potent tropic hormones, such as the adrenocorticotropic and thyrotropic hormones, and their influence on therapy is not mentioned.

Aids to Public Health. By Llywelyn Roberts, M.D., M.R.C.P., D.P.H., Medical Officer of Health, City of Sheffield. Sixth edition. Cloth. $2 Pp. 304. Baillière, Tindall & Cox, 7-8 Henrietta St., Covent Garden, London, W.C.2 [The Williams & Wilkins Company, Mt. Royal & Guilford Aves., Baltimore 2], 1950.

This book on public health briefly and superficially summarizes modern British public health practices. As a quick review of the general subject it will be useful to public health personnel, although in some respects the information and recommendations are not in accord with latest advances. The section on infectious diseases particularly needs revision, since some of the recommendations made are not accepted by most modern authorities.

Your Hair: Its Health, Beauty and Growth. By Herman Goodman, B.S., M.D. Cloth. $2.95. Pp. 287, with illustrations. Emerson Books, Inc., 251 W. 19th St., New York 11, 1950.

This edition is merely a reprinting of a book issued several years ago. In popular style, the author ranges from a discussion of the cause and treatment of various forms of alopecia to the etiological concepts and therapy of hypertrichosis. In general, the subject matter is presented in a simple manner and provides a review of facts old and new on the subject of hair and hair growth.

Einfuhrung in die pathologische Physiologie. Von Professor Dr. F. Grosse-Brockhoff, Oberarzt an der medizinischen Universitats-Klinik Bonn. Cloth. 39.60 marks. Pp. 645, with 306 illustrations. Springer-Verlag, Reichpietschufer 20, Berlin W. 35, 1950.

As the title indicates, this book is written for medical students rather than for the physician in general practice. The author aims to bring the medical student face to face with the unknowns in the physiology of disease. The numerous illustrations are excellent. The author displays good critical judgment, but in many instances he fails to list (even briefly) the proven facts on which he bases his conclusions, a method essential in elementary medical education.

QUERIES AND MINOR NOTES

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

ANGINA IN WINTER

To the Editor:—A patient with severe angina largely in winter, or in cold, damp and windy weather, wants to know whether there is a place in this country with weather or climate near ideal for him, an all-year dry, warm and sunny weather, not windy and located at sea level or moderately above it. I think the Pacific Islands might offer such a climate. Would you agree with this? Leopold J. Schwarz, M.D., Wildwood, N. J.

ANSWER.—The combination of ideal climatic conditions mentioned above is practically unobtainable. The dry, sunny areas in the southwest of this country tend to be at moderate altitudes and often windy. There are doubtless favorable places in Southern Arizona and Southern California where the altitude is not great and where there is not much wind. Southern Florida is often helpful to patients with angina pectoris in the winter, but the weather there can also be humid and windy. Possibly some desert areas of Sahara might be suitable, although there again wind storms and remoteness from civilization could be deterrents. The Pacific Islands, including Hawaii, would probably not be suitable. While the climate is equable, the humidity is relatively high and there are winds such as the trade winds of Hawaii. The conditions required may perhaps be met in the Southwest in the region around Yuma, Ariz. (altitude 140 ft.). Other areas of this type include Needles, Calif. (altitude 491 ft.), and Phoenix, Ariz. (altitude 1,100 ft.). They are, however, hot in summer.

BASKETBALL FOLLOWING RHEUMATIC FEVER

To the Editor:—Should a high school boy who has had rheumatic fever be allowed to play basketball three months after an attack, provided there is no evidence of cardiac disease? The rheumatic fever involved the right knee joint and one metacarpophalangeal joint of the left hand. There was only moderate fever during the three weeks' course of the disease. M.D., Minnesota.

ANSWER.—One of the most difficult problems in the management of rheumatic fever is to determine when the active process is at an end and how rapidly the patient should resume normal life. Even if there is no clinical or laboratory evidence of cardiac involvement, the majority of students of rheumatic fever would advocate at least two or three months of bed rest following the onset of an acute rheumatic episode. After this period, the return to full activity should be gradual. It would scarcely seem wise to permit strenuous exercise within three months of the onset of rheumatic fever.

FLUORIDE POISONING

To the Editor:—In the process of reducing aluminum ore, certain fluorine derivatives are given off which are harmful when ingested. In areas where reduction plants are located, these derivatives settle on vegetation. When the vegetation is eaten by cattle, deleterious effects on their teeth are noted. Kindly inform me where I can get literature on this subject, particularly as to the effect of these products on the human body. M.D., New York.

ANSWER.—Exposure that might lead to fluorine or fluoride poisoning is by no means limited to the smelting of ores, nor is ingestion the only avenue of possible damage. The lowest form of chronic poisoning, mottled enamel of teeth, is inaugurated only in children and is due to the imbibition of waters with a natural high content of fluorides. In industry extensive exposure results from the application of fluorides in the founding of aluminum. Some poisoning has arisen from the accidental ingestion of fluorides in pesticides. The chronic form of fluoride poisoning characterized by dense deposits in bones and tendons as revealed in roentgenograms is not known to have occurred in the United States but has been described in European countries. In a few areas, damage, chiefly to cattle, has followed volcanic eruptions. A voluminous literature descriptive of all features of fluorine and fluoride poisoning has accumulated. The newest comprehensive publication with an extensive bibliography is by J. Larner (Toxicological and Metabolic Effects of Fluorine-Containg Compounds, *Indust. Med.* 19:535 [Nov.] 1950).

FREQUENT URINATION

To the Editor:—A 77 year old man with carcinoma of the liver of about five months' duration is having frequency of urination, every one and a half hour to three hours, day and night. The urine, kidneys, ureters and prostate are normal. There are no signs of pressure on the urinary tract. A urologist and about 15 other physicians have seen the patient, but none have given any suggestion as to etiology or treatment. I will be grateful if you can advise in any way. Pains in the abdomen began after a virus infection, diagnosed as hepatitis, last March. In April the diagnosis of carcinoma was made. Later that month he was treated with roentgen rays and sodium pteroyltriglutamate. In about four days the severe pains in the liver disappeared. M.D., New Mexico.

ANSWER.—Frequent urination in the presence of normal urine may have a variety of causes. The data supplied do not permit a categorical diagnosis. Frequent urination may be of two types: first, frequency which implies the passage of small amounts of urine at short intervals with a normal 24 hour urine output; second, polyuria, which implies the passage of normal amounts of urine at short intervals with an abnormally large 24 hour urine output. Repeatedly normal urine specimens must be obtained over a period of weeks before the urine can be safely called normal. In addition, tests of the concentrating power of the kidneys must be done if casual specimens do not occasionally show a specific gravity of 1.020 or more. If there is frequency, the cause probably lies within the lower urinary tract, although neurological disease, psychogenic disturbance and disease in adjacent viscera involving the lower urinary tract must be considered. If there is polyuria, primary renal disease (e. g., renal arteriosclerosis), endocrine disease (e. g., diabetes insipidus, Addison's disease) and psychogenic factors should be considered. It is impossible to discuss here the differential diagnosis completely, but distinction between frequency and polyuria, assurance of the normality of the urine and observation of the renal concentrating power should narrow the field of diagnostic possibilities and indicate the direction for further study.

ESTROGENS FOR CANCER OF BREAST

To the Editor:—A woman aged 40, with two children, had a radical right mastectomy for breast cancer, without metastasis at that time, in January 1948. In 1949 widely diffused bone metastasis developed, and in February 1950 she had a hysterectomy and ovariectomy, to combat the bone metastasis, which had been poorly controlled with roentgen rays and testosterone in massive dose. Great improvement followed the second operation, the bone metastasis showing remarkable recalcification. The patient regained the lost weight and was energetic. The many hard nodules under the scalp shrank and disappeared. However, two subcutaneous nodules on the right hemithorax, below the amputated breast, and a nodule on the right plantar region seem not to be influenced, even by roentgen therapy. Another nodule on the right hemithorax last year was removed surgically and found to be a metastatic one. Testosterone, had to be discontinued because allergy developed. The patient is suffering from menopausal disturbances, chiefly profuse perspiration. I have tried again small doses of testosterone by mouth, with the same intolerance by the patient. She has shown the same intolerance toward progesterone, characterized mostly by temporary reactivation of bone pains. Is it hazardous to use small or large doses of estrogen to control menopause disturbances and, possibly, also influence the subcutaneous nodules? Can I use vitamin E? I will appreciate any help you may extend me. A. A. Bernardo, M.D., Philadelphia.

ANSWER.—The use of estrogen hormones to combat extensive carcinoma of the breast is reserved for women over 60 years of age. However, inasmuch as this patient has been completely castrated for 18 months, it may be that the estrogen in large doses would be of benefit. Certainly, when all other therapy has failed, it should be tried. There is no contraindication to the use of vitamin E, although its value in this situation is to be questioned. The recurrent nodules can be treated with radium application, radon implants or roentgen rays administered by means of a cone, so that the rays could be focused directly to the affected area. There are no radioactive elements known at this time which would be of any greater benefit. Further metastasis is to be expected, as temporary response to endocrine therapy will eventually be followed by recurrence and further spread of the disease, which finally results in death.

EPIDEMIC OF CONJUNCTIVITIS

To the Editor:—There has been an epidemic of a peculiar type of conjunctivitis at one of our junior high schools. Cultures from 13 of 26 eyes were positive for Actinomyces nocardia. A control group of cultures was made from 13 students in that school who had not had this conjunctivitis and 13 students from another school, where there was no epidemic. These were all negative. The three ophthalmologists who have been consulted feel that the symptoms in no way correspond with those described as typical of Actinomyces. There is rarely pus in these eyes; they are moderately red; some have extremely fine granulations along the margin of the lids; there is usually itching, a tight, uncomfortable feeling and sometimes pain. Symptoms respond to medication with sulfonamides but tend to recur if the drops are not used long enough. The epidemic has been in progress for 10 weeks in spite of the fact that pupils with the infection have been excluded, except at first, when they were allowed to return to school if they were receiving medication. About 10 days before the epidemic started some shavings were placed in a pit for jumping purposes. Similar shavings were used simultaneously in two other schools, where there has been no epidemic. The same species of A. nocardia was isolated at two different times from the shavings at this school.

Elizabeth H. Laidlaw, M.D., Tucson, Ariz.

Answer.—Actinomyces nocardia is an exceedingly uncommon but definite cause of several chronic types of keratoconjunctivitis. A variety of clinical pictures have been reported: superficial punctate keratitis, yellowish nodules on the conjunctiva, adherent yellowish white membrane on the palpebral conjunctiva, raised nodules on the surface of the cornea and sclera, chronic conjunctivitis, mucopurulent conjunctivitis, folliculosis with adenitis and bullous keratitis with granulation tissue. Probably the only characteristic ocular involvement caused by Actinomyces is chronic conjunctivitis, almost invariably unilateral, that follows concretions in the lacrymal canaliculi. Removal of the concretions by curettage, mechanical expression and irrigation is followed by complete and rapid recovery.

A. nocardia is usually considered to be a nonpathogenic soil bacterium. Many types of Actinomyces are present in the soil, and it is easily possible for some organisms to enter the eye. The pathogenicity of the entire group of organisms is low, and ordinarily only a small percentage of the population is susceptible to this type of infection. Once the infection is established, treatment is frequently unsuccessful.

If the infection has continued in this group, the following regimen is suggested. The cause must be definitely confirmed, as A. nocardia is usually of such low pathogenicity as to be a highly unlikely causative factor in conjunctivitis involving such a large group. Smears and scrapings should be made of the conjunctiva and eyelid margins. Smears should be stained by Gram's method and examined for fungi and bacteria. Scrapings should be stained by a blood stain such as Wright's or Giemsa's. The scrapings should be examined for bacteria and fungi in the epithelium, for the inclusion bodies of trachoma and inclusion conjunctivitis and the eosinophils of allergic conjunctivitis. Material from both the conjunctiva and the lid margin should be cultured under both aerobic and anaerobic conditions with several different types of mediums. Animal inoculations with A. nocardia are usually not successful.

If A. nocardia is the likeliest cause, the first step in the treatment should be irrigation of the lacrymal sac through both the superior and inferior puncta and complete assurance that there is no source of infection in the lacrymal apparatus. Drugs of choice are penicillin G and sulfadiazine administered systemically in full doses. Locally a 5 per cent sulfadiazine ointment may be of value. One should keep the lid margins free of epithelial debris by cleaning with cotton-tipped applicators.

ANTIBIOTICS EXCRETED IN BREAST MILK

To the Editor:—A mother asks whether there is any objection to her taking aureomycin or other antibiotics while nursing a baby. This mother has relapses of undulant fever, and aureomycin has proved of benefit.

Eugene T. Brunson, M.D., Ganges, Mich.

Answer.—Penicillin is excreted in the breast milk and in therapeutic amounts. Guilbeau and co-workers (Aureomycin in Obstetrics, *J. A. M. A.* 143: 520 [June 10] 1950) attempted to determine aureomycin levels in breast milk. In eight nursing women with a daily oral intake of 2 to 3 Gm. of aureomycin, it was found that the aureomycin level in the breast milk either equaled the level in maternal serum or was 12 to 25 per cent lower than in the serum. While such amounts of aureomycin might not harm the nursing infant, one wonders about the advisability of allowing a mother with chronic undulant fever to nurse her baby. If undulant fever can be transmitted through the milk of other mammals, is it not possible that it may be transmitted through human breast milk?

CHIGGERS

To the Editor:—I have had an attack of intense itching following trips to the country. The lesions were diagnosed as due to chiggers. Is there anything that can be done to prevent the bite of these mites? Kindly suggest a local application to relieve the itching and hasten involution of the lesions.

M.D., Pennsylvania.

Answer.—The secretions of the larvae of Trombicula cause dermatitis. The larvae themselves are found on the skin for only a day or two. Before the chiggers have dropped off the skin, treatment consists of a hot bath with soap and water, followed by the application of a 5 to 10 per cent sulfur ointment containing 1 per cent phenol. Accompanying pyogenic infections are treated by the use of appropriate antimicrobial agents. Mite infestations may be prevented by the use of repellents, the formula of one being as follows:

Dimethylphthalate	6 parts
Indalone (butyl mesityl oxi-oxalate)	2 parts
Rutgers *612* (*2-ethylhexanediol-1,3*)	2 parts

These are mixed mechanically. One-half teaspoonful is poured into the palm of the hand; the hands are rubbed together, and a thin layer of the mixture is applied to the face, neck, ears, hands and wrists (but not into the eyes or mouth). The application on the skin is effective for two to four hours. In addition to mites, it repels immature ticks, mosquitoes, gnats and flies. The application on garments is more lasting. It is sprayed or applied by hand and remains effective for a number of days. The impregnation of clothes with dimethylphthalate lasts still longer. They are immersed in a solution of 5 per cent dimethylphthalate and 2 per cent soap and dried. Clothes remain repellent for a month or two even though laundered.

SHOULDER PAIN FOLLOWING CORONARY ATTACK

To the Editor:—I am a victim of coronary heart disease, having had a posterior infarct in 1943. Since then I have experienced excruciating pain in the left shoulder girdle for six to 12 weeks at a time. At first the pain was ascribed to sequels of the coronary episode. In the last two years the fifth, sixth and seventh cervical vertebrae show definite arthritic changes. For some time I have taken 1/40 to 1/20 grain (1.5 to 3 mg.) of dihydromorphinone hydrochloride three times a day with relief. My heart does fairly well. I have some definite anginal attacks relieved by one or two 1/150 grain (0.40 mg.) glyceryl trinitrate tablets. The nitrites have never relieved the shoulder girdle pain. I am 61 years old and in apparently good physical condition. I have never had an acute failure episode. I am now advised that dihydromorphinone hydrochloride is strongly contraindicated. What are the contraindications to this drug in particular and narcotics in general in my case?

M.D., Kansas

Answer.—If the shoulder pain began soon after the myocardial infarction, it is likely that it was then due to reflex dystrophy initiated by the heart lesion. This rheumatic complication, however, seldom lasts as a painful condition more than six to 12 months, after which stiffness and muscular atrophy at the shoulder and hand oftentimes may remain. If severe pain persists or has become worse through the several years subsequent to the myocardial infarction and especially if roentgenographic evidence of arthritis exists in the cervical vertebrae, it is most likely that the left shoulder pain currently present is due to the spinal lesion. Severe shoulder pain resulting from disease in the cervical part of the spine usually is due to nerve root pressure and results from extensive degeneration of a cervical disk or to arthritic spurs encroaching on the foramen, or a combination of these abnormalities.

Accurate diagnosis is of first importance. When these conditions obtain, there may also be neck pain, limited cervical motion, crepitation and aggravation of shoulder pain by cervical motion. Roentgenograms will demonstrate the bone and intervertebral disk lesions, and oblique views of the cervical spine should show any encroachment on the foraminal space. Nerve root pressure often also causes paresthesia along the distribution of the nerve and sometimes reflex and/or pinpoint sensation changes.

If the condition is not too severe, usually the use of cervical traction properly applied, a Thomas collar, proper physical therapy and non-narcotic analgesia give good results. If severe localized pain occurs, injection of procaine hydrochloride at the nerve root or site of initiation of pain may be helpful although of only temporary value. If these measures fail and if pressure on a nerve root persists, sometimes it is necessary to relieve the pressure surgically. Continued use of narcotics for relief, rather than relieve the cause for the pain, is unwise. The warning against continued use of dihydromorphinone hydrochloride was undoubtedly given on this basis. The fact that the heart has continued well compensated indicates good healing of the infarction, so that it behooves the sufferer to find out the cause for the pain and correct it if possible. It is wise to have the expert help of a specialist capable in this field; consultation with orthopedist, rheumatologist, neurosurgeon and internist is advised.

SWELLING OF THE CHEEK AND PREMENSTRUAL TENSION

To the Editor:—A 22 year old woman complains of unilateral swelling of the cheek eight to 10 days after each menses. The condition has persisted about eight months. The swelling is nonpainful, lasts three days and starts in the region of the malar eminence. During the course of the three days the swelling spreads down over the cheek proper and finally disappears. There is no associated discoloration of the face or other signs of local pathology. Two years ago she underwent a Baldy-Webster suspension, tubal ligation and appendectomy. Four years ago the patient had a normal full term pregnancy, and to date her periods have been normal. Results of physical examination and routine laboratory tests were essentially negative. The patient was placed on a salt-free diet, 10 grains (0.6 Gm.) of ammonium chloride three times a day and 20,000 units of estrogens every three days for five doses. . She was not seen until the swelling recurred, three days prior to her next period. The swelling had completely abated by the first day of the menses. She received the same treatment the following month, and, while the swelling recurred again just prior to the period, it lasted only two days and was not as pronounced. During the third month under observation she was given 10 mg. of testosterone propionate twice daily for the first 15 days of the cycle. The patient had no swelling during that cycle. What would be the most likely diagnosis?

M.D., Ohio.

Answer.—The condition is part of the syndrome known as premenstrual tension. In this syndrome all types of bizzare swellings may occur in different parts of the body. The etiology of premenstrual tension has been stated to be an increased amount of estrogen in the blood before the onset of menstruation or an insufficient amount of progesterone secretion at this time. Greenhill and Freed (*Endocrinology* 26:529 [March] 1940) postulated a single mechanism for the development of the variety of changes which occur. Premenstrual distress is, according to this hypothesis, the result of sodium ion retention by the different tissues of the body under the influence of the ovarian steroids. This retention of sodium ion is associated with an increase in extracellular fluid in the tissues, which may be microscopic in amount or may develop into gross edema. Under this theory, the neurological symptoms result from edema of the nervous system, probably the brain, the nausea and bloating of the abdomen result from edema of the gut and the other symptoms arise from the specific organs affected.

On the basis of this hypothesis one could administer ammonium chloride by mouth, a salt frequently used for removal of edema fluid in cardiac and renal disturbances, although not in the usual diuretic doses. The patient is advised to refrain from adding table salt to food during the last two weeks of the menstrual cycle. During this time she is given 0.6 Gm. of ammonium chloride three times a day.

DIABETIC SUGAR FREE WHEN TAKING ALCOHOL

To the Editor:—A man aged 30 has had diabetes mellitus for five years. His blood sugar varies between 120 and 174 mg. per 100 cc. He is taking 12 units of insulin (80 units per cubic centimeter) twice daily. Sugar in the urine may be 4 plus on one test and in 20 to 30 minutes may become negative, and vice versa. This man drinks moderately, four or five drinks per day, and when he does this the urine becomes negative for sugar. During the time he is taking alcohol he is very nervous. Why is he devoid of sugar at the time he is taking alcohol?

Frank J. Burian, M.D., Williamson, W. Va.

Answer.—It is likely that the patient has no sugar in the urine while taking alcohol because of the reduced intake of food during such times. It is not possible to outline treatment properly without knowing more about this man. Information is needed regarding his weight, height, occupation, food habits and level of intelligence. However, the following general principles are suggested: 1. The diet should be reasonably constant from day to day and should allow daily 150 to 200 Gm. of carbohydrate, at least 1 Gm. of protein per kilogram of body weight and fat to maintain body weight at a satisfactory level. 2. Protamine zinc insulin should be given daily before breakfast, with the dose gaged so that the fasting blood sugar is in general in the range of 120 to 140 mg. per 100 cc. If, having attained this, the urine just before the noon meal regularly contains sugar, a dose of regular or crystalline insulin should be given in the morning before breakfast by separate injection at the same time that the dose of protamine zinc insulin is given. The dose of clear insulin should be that amount which will in general allow the urine just before the noon meal to be sugar free or nearly so without causing insulin reactions in the forenoon. According to this plan, all insulin would be taken before breakfast. With a patient of this type, it would be best at the start to give the two varieties of insulin by separate injections, reserving until later the possibility of insulin mixtures. 3. Complete abstinence from alcohol should be insisted on.

LIQUID PETROLATUM IN PERITONEAL CAVITY

To the Editor:—A woman aged 45 has had a septic temperature for three months. Pelvic examination revealed a mass in the lower left abdominal quadrant which was thought to be a tubo-ovarian abscess. A laparotomy was performed and revealed a generalized nodular process throughout the entire peritoneal cavity with considerable thickening of the terminal ileum. Although no primary site was found, the thought was that this patient had a generalized inflammatory carcinomatosis of the peritoneal cavity. However, the pathologist did not find cancer; the report stated that the excised tissue was a generalized granulomatous reaction due to a foreign body. A report of a laparotomy done 17 years previously reveals that 14 ounces of liquid petrolatum were injected into the peritoneal cavity. What treatment has been instituted in patients who have had liquid petrolatum injected into the peritoneal cavity? There were no free droplets of oil in the peritoneal cavity.

M.D., Pennsylvania.

Answer.—There is no specific treatment for diffuse granulomas of the type which you have observed following the injection of liquid petrolatum into the peritoneal cavity, particularly since no free oil was found. It is barely possible that some of the bacterial enzymes which are being investigated at present might ultimately be useful in such conditions, but it is too early to advise their use in a patient such as the one described. The chief problem in this patient will probably be relief of pain and the treatment or prevention of intestinal obstruction resulting from adhesions.

CALCIUM

To the Editor:—When is it advisable to give calcium intramuscularly or intravenously? Is such administration advisable in gastrointestinal diseases, especially those associated with diarrhea? Is administration of calcium, either orally or parenterally, indicated in tuberculosis? Is calcium useful as a so-called general tonic? Is calcium advisable in cases of malnutrition due to illness or to a constantly inadequate diet?

William L. Nute, M.D., Talas, Kayseri, Turkey.

Answer.—There is widespread unwarranted use of calcium compounds given parenterally. This practice is promoted by certain manufacturers of calcium compounds prepared for this purpose. The indications for use of calcium compounds are well stated in "New and Nonofficial Remedies," as follows: "Calcium salts are specific in the treatment of hypocalcemic tetany. Vitamin D or parathyroid hormone may also be indicated according to the etiology involved. In severe tetany, parenteral administration, preferably intravenous, is indicated to bring symptoms under rapid control. Latent tetany or mild symptoms may be controlled by oral medication. When calcium is deficient, hydrochloric acid may increase its absorption."

There is little or no ground for parenteral administration of calcium salts in gastrointestinal diseases, whether or not associated with diarrhea. The administration of calcium in tuberculosis is empirical and is not supported by adequate evidence. There is no reason to believe that calcium serves any useful purpose as a "general tonic." The administration of calcium may be indicated in cases of true calcium deficiencies, such as occurred in large numbers in the middle European countries during and after World War I. In general a remedial diet is preferable to the administration of calcium compounds.

STAIN FOR PROSTATIC SMEARS

To the Editor:—Please describe the best method of fixing and staining prostatic smears.

W. F. Bell, M.D., Rutherford, Tenn.

Answer.—The following formula is recommended for the purpose of fixing and staining prostatic smears:

A. Prepare thin smears from prostatic secretions. Do not allow to dry.

B. Fixation: Place smears while still wet in ether alcohol 20 minutes to one-half hour (equal parts 50 per cent ether, and 95 per cent alcohol).

C. Stain:

1. Place slide for two minutes in Harris' hemotoxylin diluted with an equal part of distilled water.
2. Rinse in tap water.
3. Dip three times in a 0.5 per cent solution of hydrochloric acid.
4. Wash in running water for 10 minutes.
5. Place slide in saturated solution of lithium carbonate for one-half minute.
6. Wash slide in running water for 10 minutes.
7. Dip slide in dilute eosin.
8. Rinse in tap water.
9. Dehydrate in three changes of 95 per cent alcohol and two changes of absolute alcohol.
10. Clear in two changes of carbolxylene.
11. Place in xylene for five minutes. Mount in permount or Canada balsam.

SCHIZOPHRENIA

To the Editor:—Will the following conditions contribute to the development of schizophrenia? A woman in her late thirties is confined to an institution because of schizophrenia. Her mother was much disturbed and in almost a constant state of unrest during the prenatal state. An older sister of the mother, a religious fanatic, insisted that her mother should refuse sexual relations with her husband. The patient as a young child heard much of the intrigue to separate her parents and continued to hear this up to the time when her parents were separated and divorced, when the patient was about 12 years of age. This patient was in a state of bewilderment and dismay and kept asking over and over again why this had to be. When she overheard the scheming to ruin her father's business and bring him into disrepute, she became more bewildered. The patient was married in her twenties and has two boys and a daughter. She takes no interest in her home and asks her husband for a divorce.

M.D., Indiana.

ANSWER.—In answer to the question of the possibility of prenatal influences having to bear on the development of a schizophrenic reaction, there appears to be no scientific evidence to substantiate such a premise. A significant family factor is the personality make-up of the maternal sister, who is described as a religious fanatic who insisted that the patient's mother refuse sexual relations with her husband. One wonders about the mental state of this aunt, whether she too may not have had some aberrant psychiatric traits. The cause of schizophrenia is not known, but the incidence of this mental illness in disturbed or broken homes is much greater than it is in normal homes. While the parental quarreling which resulted in the patient's being confused emotionally may have served to precipitate the schizophrenic reaction, it probably was not the actual cause. The parents were separated and divorced when the patient was 12; yet she was able to carry on to her twenties, marry and have three children. Her breakdown in the thirties is the usual period of breakdown for a patient suffering from a paranoid type of schizophrenia.

GREENISH DISCHARGE FROM BREASTS

To the Editor:—A patient with congestion of both breasts can express a greenish serous discharge from them. Other abnormalities were not found on complete physical examination. She is 35 years old with menses every 28 days, lasting one or two days, with slight midmenstrual leukorrhea. She has no children and for two years has tried to become pregnant. Advice as to treatment would be appreciated. Treatment with estrogen, dihydrostreptomycin, testosterone and progesterone has failed to reduce the congestion of the breast or the discharge from the nipple.

M.D., Connecticut.

ANSWER.—This patient presents several problems, namely, the congested breast, the discharge from the nipple and sterility. It is not unusual to find metaplasia of the breast in women of this age who have not conceived. It would be wise, therefore, to subject this woman to thorough investigation for the cause of her infertility. The outline of such an investigation can be found in any standard obstetrics and gynecology textbook. If she were to conceive, the breast, after lactation, would probably return to normal. In the meantime a great deal of relief can be afforded the patient by placing her on a salt-free diet and giving her large doses of ammonium chloride, 1 Gm. four times daily, until the breasts have softened. The discharge is probably not an infection, but this could be readily determined by examination of some of the exudate after proper preparation of the nipple before expression of secretion. Greenish serous discharge is frequently present in chronic cystic mastitis and causes the development of cysts, which are found on tissue examination. In all probability the discharge will respond to the treatment for the relief of the congestion. Further endocrine therapy should not be attempted, as it might aggravate the condition.

INFECTIOUS MONONUCLEOSIS AND BELL'S PALSY

To the Editor:—A 17 year old white girl complained of headache, fever, severe sore throat and lymphadenopathy of the cervical, axillary and inguinal areas. The spleen was palpable. Infectious mononucleosis was suspected, and a peripheral blood smear confirmed the suspicion. Her throat remained sore, and a membrane developed about two weeks after onset of the illness. A throat smear revealed only the usual organisms of the nasopharynx. Taste sensation was normal on the anterior surface of the tongue. The patient improved and was ambulatory in the third week; then peripheral Bell's palsy developed. What is the incidence of this neurological complication in mononucleosis? Could it be attributed to the prolonged sore throat in this case?

Paul A. Newton, M.D., Oakland, Calif.

ANSWER.—Central nervous system involvement in infectious mononucleosis is common. Serous meningitis, encephalitis, encephalomyelitis and isolated or diffuse upper and lower motor neuron lesions have been described. There are reports of spinal fluid changes, such as pleocytosis, increased pressure and increased protein in as high as 50 to 90 per cent of some series. Neurological changes most often occur two to four weeks after the onset of the disease; in occasional cases these have preceded adenopathy and lymphocytosis by as long as two weeks. Recovery from the neurological aspects of infectious mononucleosis is usually complete in one to four weeks, but rare instances of permanent damage have been observed. Five cases of facial palsy are found in the literature. In one of the first two, described by Gsell (1937), there was bilateral involvement. In another case, described by Zohman (1942) the disease was associated with diffuse lower motor neuron lesions. It seems probable that the palsy in the patient described is the direct result of the "neurotoxic" properties of the infectious mononucleosis virus rather than direct extension of the inflammation from the throat

SUDDEN SENSATION OF ROTATION OF OBJECTS

To the Editor:—A 56 year old man suffered suddenly, for 10 seconds, the sensation of rotation (with 45 degrees) of all objects, but only with the image of the left eye. This was accompanied with vertigo and was followed during the whole day by headache and tiredness. There were no other symptoms. All his life he had tendency to vasomotor lability. He had a positive skin reaction to brucellin and rheumatoid pains which improved with injections of brucellin. For years he had experienced attacks of mild colitis, probably of amebic origin, which had the usual treatment. Blood pressure is 140/80. General and neurological examinations do not reveal abnormalities. Wassermann and Kahn reaction of the blood were negative (one year ago). The patient smoked moderately some years ago but does not smoke at present. He takes alcoholic beverages in moderate amounts.

D. A. Hachenburg, M.D., Ecuador.

ANSWER.—Transitory rotation sensation affecting objects seen with the left eye and vertigo and headache lasting for only the one day suggest a temporary pressure inside of the right cortex; this could well be on a vascular basis, as is widely believed about similar symptoms in migraine. If it really is of the same nature as migraine, one must hesitate to draw conclusions as to the efficacy of any treatment of accompanying conditions, no matter how definite they are and/or how helpful the treatment of them has been. The symptoms could, of course, be the earliest evidence of aneurysmal pressure or brain tumor, despite the absence of significant changes.

PAIN IN FOOT

To the Editor:—Six months ago tests showed that my wife had a blood sugar level of 290 mg. per 100 cc. with extreme pain in the right leg and foot. The sugar value became normal in two days with insulin therapy. The foot became ash gray, and gangrene threatened. However, after three weeks and a sympathectomy the foot responded. Now, after six months, the foot looks well but occasional edema develops and lasts a few days. While the pain has decidedly lessened, especially during the daytime, there still remain paroxysms of pain during the night, and sleep is induced with meperidine hydrochloride. An average of 150 mg is required each night. Two months ago about 250 mg. were necessary during the night. Is there anything else available to rid this foot of pain? Multiple vitamin preparations are being used without effect. Is soaking the foot in moderately heated water objectionable?

M.D., Pennsylvania

ANSWER.—The lancinating pain at night may well be due to a diabetic neuropathy; tendon reflexes may be absent, and studies of sensation and vibratory sense are in order. Biweekly injections of vitamin B_{12} (15 gammas for each dose) have shown promise. Unless the circulation deteriorates, the nerve lesion may gradually enter a painless stage. Narcotics should be avoided at all costs. Soaking in tepid water is not objectionable but is usually without benefit and may macerate the skin

ONE SHORT LIMB

To the Editor:—A high school girl, 15½ years, weight 122 pounds, height 5 feet 4 inches, has slight curvature of the spine and a limb 1¾ inches short. The radiologist states that she has attained full growth and that there is no tuberculosis or other disease of the bones. The orthopedist has advised shortening the longer limb, which he states will entail six months in a cast and two months on crutches. This would prevent the girl's going to school this fall and graduating with her class. Would a lift overcome her condition for the present?

James R. Stringham, M.D., Cheboygan, Mich.

ANSWER.—There is no clue as to the cause of the inequality of leg length. The girl has waited too long already, but she can continue to temporize if her pelvis is properly balanced. This can be determined best by examination of the levels of the gluteal creases while she stands. This method is more accurate than any form of tape measure examination. In regard to equalization by surgical treatment, she will have to resign herself to delaying either part of her education or her vacation. She should try a platform shoe on one foot and a nonplatform shoe on the other. If she wears high heels she should add 1 inch on the short side and take ¾ inch off the normal side. If she wears low heels, she should add 1½ inches to the short side. The "make" of shoe is not as important as the size and shape. The shoe should look like her foot and have the same dimensions

EFFECT OF CORTISONE AND PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) ON RHEUMATIC DISEASES

PHILIP S. HENCH, M D
CHARLES H. SLOCUMB, M D
HOWARD F. POLLEY, M D
and
EDWARD C. KENDALL, Ph D
Rochester, Minn

The antirheumatic effects of the adrenal cortical hormone, cortisone, and of the pituitary adrenocorticotropic hormone (ACTH; corticotropin) have been demonstrated by many investigators within the past year. These beneficial effects may be produced especially on rheumatoid arthritis and acute rheumatic fever but also on several other articular conditions such as the acute arthritis of gout, the arthritis of disseminated lupus erythematosus, of psoriasis, of ulcerative colitis and to a limited extent on the arthritis of tuberculosis and in certain cases of primary osteoarthritis. In general the relief lasts only during the period of hormonal administration.

GENERAL RESULTS IN RHEUMATOID ARTHRITIS

Varying degrees of improvement have been obtained in practically all cases of active rheumatoid arthritis, rheumatoid spondylitis and Still's disease (juvenile rheumatoid arthritis) in which cortisone and pituitary adrenocorticotropic hormone have been used. Most patients, even those with severe but reversible disease, have promptly obtained decided relief. Other patients whose chronic or severe disease had produced irreversible anatomic changes have been less notably benefited. It appears that in the cases in which disappointing results were obtained small and relatively ineffective doses sometimes were used in an attempt to reduce the expense of the rather costly hormones; occasionally relatively inactive nonstandardized preparations of pituitary adrenocorticotropic hormone were used, and in a few cases the patients' adrenal glands were found (by use of the eosinopenic test of Thorn) to be poorly responsive to pituitary adrenocorticotropic hormone and therefore unable to produce sufficient amounts of endogenous cortisone to provide a satisfactory result.

In our first series of cases [1] of rheumatoid arthritis, in all of which the disease was severe, the antirheumatic effect was very marked (almost complete relief) in 12 (57 per cent) of the 21 cases in which cortisone was given, marked (75 to 90 per cent relief) in 8 (38 per cent) and moderate in 1 (5 per cent). The antirheumatic effect was very marked in 4 (67 per cent) of 6 cases in which pituitary adrenocorticotropic hormone was given and marked in the remaining 2 (33 per cent).

GENERAL PLAN OF DOSAGE

Cortisone.—Cortisone [2] was given as a crystalline suspension injected intramuscularly. The initial day's dose was 100 mg. in our first cases and 300 mg. (150 mg. into each buttock) in later cases. Thereafter 100 mg. was the usual daily dose. A single daily dose of 100 mg. appeared to be as effective as 50 mg. twice a day. On special occasions 150 or 200 mg. was given daily for two to five weeks. In our cases of severe rheumatoid arthritis daily doses of 75 mg. were usually incompletely effective; smaller doses were inadequate or totally ineffective. It recently has been observed that mild or moderately severe rheumatoid arthritis usually can be controlled satisfactorily by giving full doses until the disease is largely suppressed and thereafter by giving 35 to 65 mg. a day or 100 mg. on three days a week, such as Monday, Wednesday and Friday.[3]

Pituitary Adrenocorticotropic Hormone.—Daily doses of pituitary adrenocorticotropic hormone,[4] prepared as a fluffy powder which is dissolved in saline solution and given intramuscularly, in our cases were usually 100 mg., occasionally 45 to 140 mg. Since the drug is rapidly absorbed and utilized by the body the total daily dose must be given in divided amounts every six or eight hours. After the initial full suppressive doses have been given daily for two or three weeks, or until symptoms are largely controlled, smaller daily doses may maintain the improvement.

Recent preparations of the drug have been about twice as potent as cortisone, milligram for milligram; thus the antirheumatic effect of about 40 mg. of pituitary adrenocorticotropic hormone is about equal to that of 100 mg. of cortisone. In general, early suppressive

doses of the former drug would be about 40 to 60 mg. daily; maintenance doses, about 15 to 20 mg. daily. In the light of further experience it seems that the maintenance doses of the two hormonal agents used in our first series of cases were sometimes larger than necessary. The doses of the two hormones must be individualized.

PATTERN OF CLINICAL RELIEF

Clinical Response.—The initial pattern of clinical improvement was characteristic. Lessening of subjective symptoms began usually within two or three days, sometimes within a few hours after the first injection of one or the other hormone. Within a few days there were appreciable reduction of muscular and articular stiffness, lessening of articular tenderness, aching and pain on motion, and usually reduction of articular swelling. In general, within the first week stiffness, aching and pain on motion were greatly relieved; within the second week articular tenderness was reduced or disappeared and articular swellings began to diminish.

Thereafter, the use of either of the hormones being continued, further improvement was more gradual, sometimes being interrupted by minor flares, "arthritis in miniature." The maximal over-all improvement sometimes developed after two or three months of administration of the hormones.

Patients often noted, coincident with the improvement of joints and muscles, increased strength, a sense of lessened toxemia, improved nutrition with increased appetite and nutritional gains in weight, and euphoria or a sense of well-being which often expressed itself by increased mental and physical energy. Fever, if present, usually disappeared. Rheumatoid nodules and enlarged lymph nodes sometimes diminished in size; a few small ones seemed to disappear. Flexion contractures usually diminished; if they were not too long established they often disappeared, frequently within three weeks.

Biochemical and Metabolic Effects.—Sedimentation rates were reduced, often to normal values. The concentrations of hemoglobin of anemic arthritics often increased, as did erythrocyte counts. Total leukocyte counts usually increased slightly. Eosinophil counts were decidedly reduced by pituitary adrenocorticotropic hormone, but were not altered consistently by cortisone. When hyperglobulinemia was present, reduction of serum globulin usually occurred and albumin-globulin ratios tended to return toward normal. Urinary 17-ketosteroids were reduced by cortisone (100 mg. doses) and decidedly increased by pituitary adrenocorticotropic hormone. The excretion of corticosteroids in urine was increased by either hormone.

Daily doses of 100 mg. of cortisone usually did not produce significant alteration in the concentrations of electrolytes in blood or tissues, but the administration of 200 mg. of the drug daily for two weeks or more sometimes produced an increased excretion of potassium and chlorides with a resultant hypopotassemic, hypochloremic alkalosis.[5]

Histological Changes.—Biopsy of synovial tissues removed before and at various times during the use of either of the hormones indicated that synovial inflammation was reduced thereby. Histological improvement was mild, moderate or pronounced, depending on how long the hormones were given and on the patient's individual response to them. The synovial tissues, though practically always improved, were not fully restored to normal. Improvement consisted of reduction in the cellular reaction with decreased number of plasma cells and lymphocytes, reduction of papillary tufting, reduction or absence of deposition of fibrin, lessened edema, and evidence of fibrous healing.

WITHDRAWAL OF THE HORMONES

When the use of cortisone or pituitary adrenocorticotropic hormone was discontinued, rheumatic activity returned rather quickly in about 75 per cent of our cases, but in about one fourth of the cases the relapses were delayed for some months. These will be reported in the section on "Optimal After-Effects."

SIDE EFFECTS OF THE HORMONES

Incidence.—These potent hormones are capable of affecting many bodily functions and many tissues other than those of joints and muscles. Some of the results are desirable but others are not. About 40 per cent of our first group of patients had no significant side effects; these patients received cortisone or pituitary adrenocorticotropic hormone for three weeks to four and a half months. Mild side effects such as mild acneform eruption, mild hypertrichosis, rounding of the face or mild irritability developed among 35 per cent of the patients who received one of the hormones continuously or almost continuously for 11 days to seven months. More disturbing side effects developed in the remaining 25 per cent during the administration of one of the hormones 12 to 187 days.

The undesirable effects usually developed in patients who received the hormones in what we now regard as high doses (200 mg. of cortisone or 100 mg. of pituitary adrenocorticotropic hormone daily) or received smaller doses, usually 100 mg. of cortisone daily, for relatively long periods. Individual tolerance also played a role, and men tolerated the two hormones better than women, especially adolescent or menopausal females.

Types.—The commoner side effects consisted of minor alterations of psyche (euphoria, mild nervousness and restless energy) and certain transient paresthesias or somatic symptoms resembling those considered functional. The paresthesias and somatic symptoms may have resulted from transient vasomotor changes or transient alterations in tissue fluids and electrolytes. Some rounding of the face was encountered not infrequently. Occasionally mild hypertrichosis, transient decrease of libido or some muscular weakness and lassitude developed; the last two were sometimes associated with hypopotassemic hypochloremic alkalosis, sometimes not.

These hormones may induce retention of salt and water indicated by sudden gains in weight with or without visible edema. Cortisone appears to possess this property less than does pituitary adrenocorticotropic hormone; this may or may not be a matter of relative dosage. When significant retention occurred, it usually developed early in the course of hormonal usage. Sometimes some degree of fluid retention persisted as long as the hormones were given, but more often an initial retention was transient and soon disappeared even though dosage was unchanged. Two patients who received cortisone had acneform eruption or folliculitis. Amenorrhea, red striae over thighs and increased retrocervical fat (buffalo hump) each developed in 1 case.

Although these hormones, especially pituitary adrenocorticotropic hormone, may notably increase the blood pressure of patients with hypertension, renal disease or conditions associated with renal lesions (for example, disseminated lupus erythematosus), significant increases of blood pressure did not develop in any of our rheumatoid patients.

Exceedingly large doses of either hormone may induce hyperglycemia and glycosuria in rats. These hormones, in certain doses and under certain conditions, may temporarily impair carbohydrate tolerance. It would appear, however, that either hormone, given in the dose range used in our cases to rheumatoid patients without latent or frank diabetes, does not reduce carbohydrate tolerance to a clinically significant degree. Whatever impairment of carbohydrate tolerance may have resulted from cortisone therapy in our patients was slight. During the use of cortisone abnormal sugar tolerance tests were noted in 5 cases, but in none of our cases did significant glycosuria or fasting hyperglycemia develop. Diabetes and rheumatoid arthritis seldom coexist, but for rheumatic or nonrheumatic patients with latent or frank diabetes these hormones should be expected to induce more pronounced reduction of carbohydrate tolerance. Such a case, that of a diabetic patient with rheumatoid arthritis, was recently reported.[3b]

One of the more interesting effects of these hormones is that on the psyche of rheumatic or nonrheumatic (nonpsychotic) patients. Rome and Braceland[6] have described four categories which encompass the range of psychologic response which attends this treatment. In grade 1 are included those patients who respond to the symptomatic relief with a feeling of well-being, a sense of increased physical and psychological capacity for constructive work which is proportionate to the subjective and objective changes produced. Several of our patients with rheumatoid arthritis may be placed in this category. A response, grade 2, differs only in its quantitative aspects. The thinking and behavioral processes are more accelerated, the amplitude of mood change is greater, and it is evident grossly that these patients are stimulated. Such responses were experienced by several of our rheumatoid patients. A grade 3 response is prone to develop in those nonrheumatic or rheumatic patients whose personality appraisals reveal evidence of previous and severe psychologic conflict. Their response to either hormone is descriptively similar to their past response to environmental stress of different sorts. Patients with cyclothymic personalities experienced mild hypomania or mild depressions, or both, whereas the obsessive person tended to have phobia states and other ruminative preoccupations. We have seen such a reaction by only 1 rheumatoid patient, a woman who received 100 mg. of cortisone daily for 187 days; after about five months changes in mood and then depression developed. These disappeared rather quickly after the use of cortisone was discontinued.

A grade 4 response is a relatively rare sequel. It has not been encountered in our cases of either rheumatoid arthritis or rheumatic fever. It comprises overtly psychotic responses characterized by delusionary thinking, hallucinations, confusion, mood appropriate to the content of thought and an acceleration in the stream of mental productivity. It is of brief duration, and after the discontinuation of hormonal therapy the grossly psychotic symptoms and signs subside within two weeks. Again there is evidence that the most prominent factor in the determination of this response is the patient's prepsychotic personality.

In summary, the physical, biochemical and metabolic changes which these hormones induce constitute, according to Rome and Braceland, a radical change in the integration of the entire organism. This change assumes the proportions of a stress comparable to the more usual physical and environmental stresses which provoke these same kinds of psychologic reactions in equally vulnerable persons. How a given rheumatic or nonrheumatic patient may react psychologically to one of the hormones can be found in an appraisal of the manner in which he has adjusted previously to other stress situations, such as severe fever, acute or chronic illness, financial, domestic or personal difficulties. Rheumatoid patients seldom have psychotic reactions as a result of the pains, frustration, economic insecurity, fear of dependency and therapeutic adventures which their disease entails. Hence, one would hardly expect a grade 4 reaction to the "stress" provided by the use of these hormones. Although grade 4 reactions have been observed in 1 of our cases of severe psoriasis and psoriatic arthritis and in 3 of severe disseminated lupus, such reactions have not been encountered so far among our cases of rheumatoid arthritis.

Posthormonal (Withdrawal) Phenomena.—In several of our patients about two or three weeks after withdrawal of hormones muscular weakness and fatigue developed, lasted two or more weeks and then disappeared. In these cases the use of cortisone or of pituitary adrenocorticotropic hormone had been discontinued abruptly without tapering off the doses. Temporary reduction of function of the adrenal cortex was considered a possible cause.

Theoretical Possibilities.—Repeated injections of pituitary adrenocorticotropic hormone produce adrenal hypertrophy, and repeated injections of cortisone produce adrenal atrophy. Hence it has been suggested that the stimulation of adrenal glands by the former drug or the inhibitive effect of exogenous cortisone on the adrenals beyond a certain limit might lead to a temporary or to a more or less permanent exhaustion of the adrenal cortex which could be serious in the face of subsequent stress. Further experience will determine the likelihood of such possibilities. But the known recuperative powers of adrenal glands which have been atrophic for years in consequence of longstanding (pituitary or adrenal) Cushing's disease permit one to conjecture that the prolonged use of exogenous pituitary adrenocorticotropic hormone or cortisone, if given in amounts that can be shown to be not too excessive physiologically, will not induce irreversible clinicopathological consequences.

Reversibility and Control of Side Effects.—All the reported side effects observed to date by us and others have been transient and reversible. In most instances the reversibility has developed rapidly as soon as the doses were reduced in amount or discontinued. Control of side effects will be discussed later in this paper.

USE OF HORMONES IN OTHER RHEUMATIC AND ARTICULAR CONDITIONS

For reasons stated elsewhere[1] we have given cortisone or pituitary adrenocorticotropic hormone to patients who had other rheumatic and articular conditions besides rheumatoid arthritis.

Acute Rheumatic Fever.—With our colleagues, Drs. Barnes and Smith,[7] we have given cortisone or pituitary adrenocorticotropic hormone to several patients who had acute rheumatic fever and to a few who had severe rheumatic carditis and cardiac failure. Daily doses of the former were usually 200 mg. for the first several days, later usually 100 mg.; total doses ranged from about 1.2 to 7.4 Gm. within three to nine weeks. Daily doses of the latter were 25 to 60 mg. for the first several days, usually 45 mg.; later daily doses decreased to 10 to 15 mg. Total doses ranged from 409 mg. to 1.4 Gm. given within two to eight weeks.

The acute manifestations of rheumatic fever were quickly abolished. Fever, acute polyarthritis and tachycardia usually disappeared within five days or less. Prolonged P-R intervals in the electrocardiogram usually became normal within three weeks or less. Sedimentation rates and hyperglobulinemia were reduced; rates became normal in an average of about 18 days. When the hormones were not given long enough there were short, usually mild, rheumatic recurrences: these consisted sometimes of transient increases of sedimentation rate, pulse rate or P-R interval, or all three, without fever or articular symptoms; sometimes the fever and articular symptoms also recurred. When the hormones were given again these recurrences disappeared.

What might be called the acute rheumatic state (that period during which the unknown irritant of rheumatic fever operates to produce in affected responsive tissues inflammatory reactions of an exudative and proliferative type) may last about six to 12 weeks. The hormones do not remove this irritant, hence they do not shorten the acute rheumatic stage. However, they appear to protect the affected tissues against the irritant; consequently the abnormal physiological processes which characterize the disease subside, and the clinical and laboratory manifestations disappear. This protection continues as long as the hormones are administered, even though the underlying and now essentially symptomless acute rheumatic state has not yet run its course.

With this concept in mind it can be understood why hormones must be given (or if their use has been discontinued prematurely, readministered) until persistently negative clinical and laboratory data indicate that the acute rheumatic state has passed. Because cardiac muscle and fibrous tissue of heart valves are not much different from the skeletal muscle and fibrous tissues which are so promptly benefited in rheumatoid arthritis, it is hoped that the proper use of these hormones may prevent or modify the development of the cardiac complications of acute rheumatic fever. Reexamination of the hearts of these patients several months after use of the hormones was stopped revealed no definite evidence of new or increased old rheumatic carditis [7b, c] except in 2 patients, each of whom had just experienced another attack of acute rheumatic fever. To prevent such recurrences our revised policy involves consideration of chemoprophylaxis. There is reason to hope that the combination of hormonal usage during the acute stage of the disease plus the subsequent prophylactic oral use of penicillin or sulfonamides may provide greater cardiac protection than has been possible heretofore. Further prolonged observations must be made to determine the value of such a plan. Further data on this problem are being reported elsewhere.[7c]

Other Articular Conditions.—In several cases of lupus erythematosus disseminatus use of either of the hormones was accompanied with temporary disappearance not only of arthritis but also of fever, skin reactions, pericarditis, pleurisy and leukopenia.[8] Renal lesions and albuminuria, if present, appeared to be unaffected. Sometimes severe cardiac lesions have been unresponsive and blood pressure has increased. Although these hormones have not been as beneficial in lupus erythematosus disseminatus as in rheumatoid arthritis, they appear to be helpful often, perhaps even life saving in acute crises. Temporary remissions, not cures, were induced.

Psoriatic arthritis has been, in our experience, more responsive to these hormones than the associated psoriasis, which has disappeared temporarily when fairly large doses were given.[9] In tuberculous arthritis (two cases) articular symptoms and signs and sedimentation rates decreased notably but results of articular biopsy, guinea pig test and cultures remained positive.

To conserve the hormones for use in more serious conditions they have been administered by us or others in only a few cases of osteoarthritis. One of our patients with leukemia and preexisting primary osteoarthritis obtained from cortisone articular relief which was maintained for some time after use of the hormone was discontinued. The articular symptoms and sometimes the intestinal symptoms of chronic ulcerative colitis have been responsive to these hormones in some cases.[10]

Independent investigations on the effect of pituitary adrenocorticotropic hormone on quiescent gout and acute gouty arthritis have been carried out by Robinson, Conn, Block, Louis and Katz,[11] by Hellman [12] and by Wolfson and his associates.[13] A close relationship between gouty arthritis and the function of adrenal cortex was demonstrated. Pituitary adrenocorticotropic hormone provoked attacks of acute gouty arthritis in patients with quiescent gout but also promptly relieved patients with acute gouty arthritis. Rapid amelioration of acute gouty arthritis by the use of this drug or of cortisone has since been reported by others.[11] Confirmatory observations on the effects of either drug on these various rheumatic and articular conditions have been made by a number of investigators.

MODE OF ACTION

How these two hormones produce their antirheumatic effect is still not clear. Rheumatoid arthritis is not a feature or complication of Addison's disease; indeed, rheumatoid arthritis and Addison's disease seldom coexist. The antirheumatic action of these hormones is not seemingly dependent on any of their metabolic or biochemical effects so far demonstrated. The adrenal glands of most rheumatoid patients under the stimulation of injected (exogenous) pituitary adrenocorticotropic hormone can apparently produce amounts of cortisone or a cortisone-like steroid sufficient to suppress the rheumatic manifestations. How much antirheumatic steroid these adrenals are producing without artificial stimulation or to what extent they are capable of responding spontaneously to sudden increases in tissue needs remains to be determined.

If there is no absolute deficiency of cortisone in rheumatoid arthritis perhaps there is a relative deficiency, one concerned with an increased destruction or with an increased tissue requirement for cortisone rather than with decreased production. Does pregnancy relieve rheumatoid arthritis by an increased production of cortisone or cortisone-like steroid? Does jaundice produce its ameliorating effects by lessening the inactivation or destruction of cortisone or by improving the utilization of cortisone at the tissue level? How does chrysotherapy benefit rheumatoid patients, through some influence on the pituitary-adrenal axis or by an entirely different mechanism involving fibroarticular tissues? Intensive study of these mechanisms of relief should be fruitful.

The fact that the effects of cortisone and pituitary adrenocorticotropic hormone are not disease specific but group specific (for example, antirheumatic and antiallergic) and demonstrable in a number of loosely related conditions (collagen diseases) suggests that the hormones act at the tissue level in some as yet unknown manner. They do not kill germs or cure any of the diseases whose symptoms they suppress; they appear instead to provide the susceptible tissues with a shieldlike buffer against the various irritants.

CLINICAL LIMITATIONS

These hormones (like substance X of jaundice or pregnancy) appear to have the power of controlling or reversing the physiological abnormalities of the diseases under discussion, in consequence of which the tissue reactions subside. These tissue reactions not only provide most of the symptoms of the disease but, if they are long continued, lead to proliferative and reparative histological changes which produce, for example, the "rheumatoid joint" or the chronic rheumatic heart These reparative changes are responsible for the pathologicoanatomic residues of the diseases, and they are not only largely irreversible but unaffected by cortisone or pituitary adrenocorticotropic hormone. Therefore, to obtain the best results the hormones should be used early, before irreversible changes in tissue have developed. With these distinctions in mind, it will be understood why the hormones may provide much more relief in a case of severe but early reversible rheumatoid arthritis than in a case of old arthritis of relatively slight (physiological) activity, in which articular (anatomical) residues are considerable. So, too, better results have been obtained in severe acute rheumatic fever with acute carditis than in less severe rheumatic fever superimposed on old damaged hearts. In short, it is the disease, not the residues of disease, which these hormones influence beneficially. To use a figure of speech, the hormones act like a fire suppressor or fire shield; they do not extinguish the fire, nor do they act as carpenters to repair the fire's damage.

PRACTICAL CONSIDERATIONS

Before these hormones can assume the role not merely of investigative agents but of acceptable therapeutic measures, certain practical problems must be solved. Sufficient amounts of cortisone and pituitary adrenocorticotropic hormone must become available and optimal methods of administration must be devised whereby the patient may receive the greatest antirheumatic effect at the least cost in terms of unwanted side effects.

Production of the Hormones.—In the matter of production great strides have been made by the two chief manufacturers of these hormones. Production schedules are far ahead of those considered possible a few months ago. Despite the fact that no new source of cortisone and no actual shortening of the method for its partial synthesis have yet been discovered, improvements in several of the 38 chemical procedures required for its production from desoxycholic acid have increased the ultimate yield satisfactorily. Methods for the preparation of pituitary adrenocorticotropic hormone also have been improved, and the potency and purity of current preparations have been increased. Several investigators[15] have developed peptide fragments of the hormone which retain the antirheumatic property, possess a molecular weight of only about 1,000 (as compared to 20,000 for the parent product) and give a basis for hoping that eventual synthesis of a potent peptide fragment may be accomplished. Meanwhile it is reported that the production of cortisone is forty-five times greater and that of pituitary adrenocorticotropic hormone is thirty times greater than it was a few short months ago. Prices have been reduced, other companies with large facilities are entering the field, and the future looks bright. But impatient rheumatic sufferers want the future now. Great efforts have been expended in the search for steroids related to cortisone which might not only be more available and cheaper, perhaps subject to total synthesis, but also possess antirheumatic properties and be devoid of side effects.

Effect of Steroids Related to Cortisone.—Many steroids more or less closely related to cortisone have been prepared for clinical testing. In the Mayo Clinic's section on rheumatic diseases we have tested 12 of them; results have been reported by Polley and Mason.[16] Ten of them belonged, like cortisone, to the Δ^4-pregnene series and differed from cortisone by variations at the carbon-11 or carbon-17 position or at both, by a single change in the side chain, by changes at both carbon-11 and in a side chain or by changes in the degree of saturation in the A and B rings. In other words, several of them were cortisone except for a single alteration. Despite this nine of them were ineffective in rheumatoid arthritis although given in amounts comparable to effective doses of cortisone. Also ineffective in our hands and in those of certain other rheumatologists were two more preparations which were recommended as possible substitutes for cortisone, namely, Δ^5-pregnenolone and 21-acetoxy-pregnenolone, known commercially also as natolone and artisone respectively. Belonging to the Δ^5-pregnene series they are much more distantly related chemically to cortisone than the other ineffective steroids just mentioned. Early favorable reports on progesterone and testosterone propionate have not been confirmed. Several other steroids have recently been reported as being ineffective.[17]

The only steroid besides cortisone that we have found to possess significant or comparable antirheumatic activity is 17-hydroxycorticosterone, Kendall's compound F.[18] Supplies of this material are so scarce that we have been able to give it so far to only 2 rheumatoid patients. It has decided antirheumatic properties, but whether they are greater or lesser than those of cortisone remains to be determined. Since its production is more difficult than that of cortisone compound F offers no early solution to the present problem of inadequate supply.

Effect of Adrenal Cortex Extracts.—We have administered to a few rheumatoid patients four extracts of adrenal cortex.[16] Two were ineffective (Kendall's extract and Upjohn's lipo-adrenal cortex extract, double strength). One concentrated extract (adrenal cortex extract[18] in propylene glycol, twenty strength) possessed mild antirheumatic activity, but a specially prepared highly concentrated extract, given in capsules orally, demonstrated pronounced antirheumatic properties. The potency of this preparation was in all likelihood based on its content of compounds E and F. It is of considerable significance that this preparation, containing compounds E (cortisone) and F, was potent when given orally. This confirms certain animal experiments which have led to the conclusion that cortisone may be effective when given by mouth.[19]

Effect of Other Substances.—Earlier favorable European and British reports on the supposed effectiveness of desoxycorticosterone acetate given with vitamin C (ascorbic acid) have been outnumbered by more recent unfavorable reports.[20] Use of this combination was investigated by our associate Dr. Paul Bilka,[21] who observed no objective changes or significant effect on sedimentation rates in several rheumatoid patients. Such transient subjective improvement as developed occasionally was no greater than that obtained by giving desoxycorticosterone and vitamin C in half the recommended dosage, by giving desoxycorticosterone followed by an injection of saline solution (without vitamin C) or by giving saline solution (without desoxycorticosterone) followed by vitamin C, or even by giving two consecutive injections of saline solution. The hope that injections of epinephrine might stimulate the production in patients of significant amounts of cortisone has not materialized.[22]

SPECIFICITY OF CORTISONE

The negative results with these various steroids indicate that cortisone possesses a high degree of physiologic specificity approached only by 17-hydroxycorticosterone (compound F of Kendall), which differs from cortisone only in that at the important carbon-11 position there is a hydroxyl radical in place of the ketone group.

ANTIRHEUMATIC PROPERTIES OF STEROIDS

From their study Polley and Mason concluded that the antirheumatic properties of the steroid structure are dependent on the presence of a ketone group at carbon-3, either a ketone or a hydroxyl group at carbon-11, a ketone group at carbon-20, a hydroxyl group at carbon-17 and at carbon-21 and a double bond between carbon atoms 4 and 5.

OPTIMAL DOSAGE AND METHOD OF HORMONAL ADMINISTRATION

Further experience is needed to determine the optimal dosage and methods of administration of cortisone and pituitary adrenocorticotropic hormone. Present procedures are tentative.

Acute Rheumatic Fever.—For the investigative management of acute rheumatic fever the hormones should be given at first in full suppressive doses, perhaps 200 mg. of cortisone or about 60 mg. of pituitary adrenocorticotropic hormone daily until the symptoms have largely or completely disappeared and the sedimentation rate has approached normal. This may take 10 to 20 days. Then smaller maintenance doses should be given for one or two more weeks: about 100 mg of cortisone or about 30 mg. of pituitary adrenocorticotropic hormone daily. The patient should then be carefully watched for another two weeks or so, and if any signs of rheumatic activity recur (any one or more of the following: rising sedimentation rate; fever; significant increases in resting pulse rate or P-R interval, or return of articular symptoms) one or the other agent should be given again in fairly generous doses for perhaps 10 to 20 days more. The doses required for children approximate those needed for adults, and the usual pediatric formulas for calculating doses do not fully apply.

[22] Thorn and others[14b] Edström[17a] Smith[17c]

In summary, the hormones should be given first in full suppressive doses, then in smaller maintenance doses until it is evident that the underlying acute rheumatic state has disappeared. Consideration should then be given to subsequent prolonged chemoprophylaxis, for example, with penicillin given orally. Because in cases of acute rheumatic fever the hormones need apparently to be given for only a relatively short time, a few weeks, the occurrence of side effects may not provide a significant problem. If minor side effects develop (round face, striae, transient amenorrhea or folliculitis) they can generally be ignored in behalf of the patient's over-all needs. If troublesome edema or other major side effects develop, measures to be mentioned hereafter may suffice to control them.

Rheumatoid Arthritis.—Studies on the development of optimal methods for administering the hormones in the face of chronic rheumatoid arthritis (or other chronic diseases) fall into two groups: the development of (1) a method whereby the results of a relatively short course of hormone administration can be prolonged significantly or (2) a method whereby the hormones can be given more or less continuously without the development of significant side effects.

Optimal After-Effects: As stated previously, about 25 per cent of our rheumatoid patients (first series) obtained pronounced relief which continued (or after a short relapse returned) after the use of the hormones was discontinued. Let us reexamine the methods of administration used in these cases [1] in which after-effects were optimal.

One patient retained relief for only four days after her first eight day course of cortisone (100 mg. daily); after a subsequent 12 day course of pituitary adrenocorticotropic hormone she had a short (four day) relapse and then regained much relief but it lasted only two weeks. After a third (18 day) course of 200 mg. of cortisone daily she retained appreciable relief for seven months.

A second patient was given pituitary adrenocorticotropic hormone for 87 days. Thereafter he has maintained most of his relief to date (nine and a half months).

A third patient was given a long course of cortisone (133 days) after which he had a mild relapse for a month, then regained and maintained almost complete relief for 11 months until influenza precipitated a relapse.

A fourth patient received two long courses of cortisone in suboptimal but progressively effective doses. The first course lasted 75 days; after an interval of 17 days, during which he had a partial relapse, a second course of 140 days was given (total 215 days of cortisone). After this he had a mild relapse, but after 12 months he is still (to date) retaining 80 per cent of the hormonal relief.

A fifth patient who on admission was confined to a wheelchair received cortisone for 25 days, after which she retained most of her decided relief for 14 months

In summary the excellent after-effects in these five cases followed no one method of administration. In one case they followed a single short course, in another case three short courses in which pituitary adrenocorticotropic hormone alternated with cortisone, and in the three remaining cases one or two fairly long courses. Thus no particular course or method emerges as obviously superior.

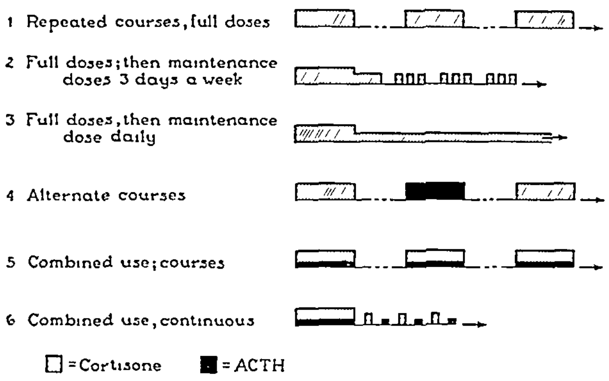
Were these posthormonal remissions spontaneous or related to the use of the hormones? Is 25 per cent the incidence rate of spontaneous remissions which should be expected even in such a group of cases of severe and previously progressive rheumatoid arthritis? Were these patients' symptoms suppressed until a spontaneous remission was due, or were these hormones and the method of their use responsible for the satisfactory after-effects? Further experience must determine the answers to these questions.

METHODS OF ADMINISTRATION UNDER INVESTIGATION

The following methods of administration require further investigation and comparison (see the accompanying illustration):

Repeated Short Courses of Cortisone or Pituitary Adrenocorticotropic Hormone.—Patients so managed would have few if any significant side effects, and the cost would be materially reduced although some relapse should be expected between courses. Whether or not the posthormonal periods of relief would often become successively longer seems uncertain at this time (plan 1 of the illustration).

Alternating Short Courses.—Under this scheme the patient is given a short course of cortisone (until the disease is largely suppressed), then a free interval, then a course of pituitary adrenocorticotropic hormone, another free interval, then more cortisone and so on. The response to such a plan was progressively satisfactory in one case, not unusual in another case. This plan has the advantages and disadvantages of the first plan with an added theoretical advantage: Whatever transient adrenal atrophy and cortical inhibition may result from use of cortisone may be repeatedly neutralized or overcome by the subsequent use of pituitary adrenocorticotropic hormone; in turn the adrenal hypertrophy and hyperplasia induced by the latter agent may be more promptly reduced by the next course of the former (plan 4).



1 Repeated courses, full doses
2 Full doses; then maintenance doses 3 days a week
3 Full doses, then maintenance dose daily
4 Alternate courses
5 Combined use; courses
6 Combined use, continuous
☐ = Cortisone
■ = ACTH

The optimal method of administration of cortisone or pituitary adrenocorticotropic hormone (ACTH) in the investigative management of chronic diseases such as rheumatoid arthritis has not yet been established. Several different plans of administration are under investigation (see text).

More or Less Continuous Administration of One or the Other Hormone.—Two variants are being studied: (*a*) Some patients have been given full suppressive doses at first and later smaller maintenance doses daily (plan 3). (*b*) Other patients, after the early period of daily suppressive doses, have done well on maintenance doses given only three days a week, for example, on Monday, Wednesday and Friday (plan 2) [8a,c] Larger maintenance doses may be required for this scheme than for the first variant (plan 3).

Other Modifications.—Two other modifications of the three plans of administration thus far investigated are under consideration. These are: repeated short courses of cortisone combined with pituitary adrenocorticotropic hormone and a suppressive course of the combined hormones followed by smaller maintenance doses of each continued indefinitely. These plans have the supposed advantage of plan 2 plus the theoretical possibility that a more nearly balanced and perhaps more effective cortical secretion might be provided. The value of these last two plans (5 and 6) remains to be proved.

Augmented Administration.—Certain workers have expressed the hope that some substance (gold salts, salicylates, vitamin C or other steroid) might be found which would augment or enhance the effect of doses of cortisone or pituitary adrenocorticotropic hormone which were so small that no side effects would develop. Our experience with salicylates and vitamin C given during courses of these hormones has been disappointing; no potentiation of cortisone was observed.

METHODS OF WITHDRAWAL

Sudden withdrawal of either hormone may be followed by a relatively short period of annoying weakness, occasionally by a "rebound relapse" of articular symptoms. These phenomena are presumably due to the temporary inhibition of adrenal cortex function which use of the exogenous hormones induces. This posthormonal period of relative adrenocortical insufficiency disappears fairly soon. To minimize it two methods of withdrawal have been suggested: (1) to taper off the daily doses of either of the hormones, giving successively smaller doses the last few (seven to 10) days and (2) to conclude a course of cortisone by giving pituitary adrenocorticotropic hormone for a few days.

PREVENTION AND CONTROL OF SIDE EFFECTS

When the prolonged use of cortisone or pituitary adrenocorticotropic hormone appears necessary (for example, in the investigative management of rheumatoid arthritis) the following procedures will help to prevent, minimize or counteract adverse side effects. When the early suppressive doses have brought the symptoms of the disease largely under control, as soon as possible the smallest effective maintenance doses should be used. Suppression of subjective symptoms, and not necessarily normalization of sedimentation rates also, should be considered sufficient. If the doses needed for full symptomatic relief begin to produce significant side effects, the dosage should be reduced and physician and patient alike should be content with less than full suppression of the disease.

If significant edema develops or persists, a reduced intake of sodium chloride (1 Gm. or less daily for adults) or the oral use of a diuretic such as potassium nitrate (2 Gm. or more three times a day) or both may suffice. For one menopausal woman [1] the administration of estrogen, 5 mg. twice a week, during a second course of cortisone prevented the development of several side effects (among them round face, hypertrichosis and nervousness) which had occurred during the first course. Further studies with estrogen are being made. Significant imbalance of electrolytes will not often occur when the daily doses of cortisone are 100 mg. or less, of pituitary adrenocorticotropic hormone 40 mg. or less, and especially when patients are eating at will rather than having dietary restrictions incident to metabolic studies. If hypopotassemic, hypochloremic alkalosis does occur (with or without muscular weakness, hypertension and electrocardiographic alterations) the oral administration of potassium chloride, 1 or 2 Gm. three times a day, is indicated. Significant nitrogen deficits will probably not develop in the rheumatoid patients who are on unrestricted diets and who are not receiving the larger doses of the hormones. If significant loss of weight and weakness should develop, an increased intake of nitrogen will probably suffice. Testosterone propionate, 25 mg. given intramuscularly daily, in 1 case prevented the nitrogen deficit produced by large doses of cortisone.[5] Testosterone propionate can be given sublingually.

The minor alterations of psyche (grades 1 and 2) need no treatment. The changes described as a grade 3 response may require the establishment of a psychological regimen comparable to that which would be needed to manage the same kind of reaction in other clinical settings. Such adjuncts as sedation, a fixed schedule of activities and the opportunity to discuss basic psychological difficulties can provide a support which may make the continuation of hormonal usage possible. Cessation of hormonal therapy removes the provocative component. Obviously the treatment of the fundamental psychiatric problem needs a special approach. In our experience a frank psychotic response (grade 4) is infrequent and is only likely to occur in patients who are psychologically vulnerable. The hormones should be used with caution for patients with previous history of a psychosis or other evidence of pronounced instability. The management of a hormonally precipitated psychotic episode requires specifically indicated measures to control the response, including the withdrawal of the hormone.[6] Measures to prevent or control postcortisone weakness have been mentioned under "Methods of Withdrawal."

SUMMARY AND CONCLUSIONS

The antirheumatic properties of cortisone and pituitary adrenocorticotropic hormone (ACTH) have been confirmed by several groups of investigators.

During the time of their administration, these hormones have exerted a decidedly suppressive effect on the clinical and biochemical manifestations of rheumatoid arthritis. When the use of the hormones is discontinued symptoms recur rather promptly in most cases, but in several of our cases pronounced improvement has persisted for several (seven to 14) months. The optimal dosage and methods of administration of these hormones for the investigative management of a chronic disease such as rheumatoid arthritis remain to be determined. Several schemes are under investigation. Rather prolonged relief with minimal side effects has been provided in some cases by the continued use of small maintenance doses after the earlier use of larger suppressive doses.

Cortisone or pituitary adrenocorticotropic hormone generally abolishes quickly the manifestations of acute rheumatic fever. There is reason to believe that the lesions of acute rheumatic carditis also are suppressed, in consequence of which the prevention of certain chronic cardiac lesions may be anticipated with some confidence, especially if adequate hormonal usage during the acute rheumatic state is followed by prolonged chemoprophylaxis (for example, with penicillin given orally). The articular complications of disseminated lupus erythematosus and psoriasis are responsive to these hormones. Limited results were obtained in 2 cases of tuberculous arthritis.

These hormones are powerful agents which may affect many functions and tissues of the body besides those of joints and muscles. Their prolonged use, at least in certain doses, may produce certain undesirable effects. These side effects have, to date, been transient and reversible. Certain measures have been developed to minimize or control some of them, but these effects *still constitute an important problem for further inves-*

tigation. If control of the side effects is not adequate in any given case, smaller doses of the hormones should be used and patient and physician alike should be content with a reduced amount of symptomatic relief.

With the exception of 17-hydroxycorticosterone (compound F of Kendall), none of the currently available steroids chemically related to cortisone appears to have significant antirheumatic properties. The oral administration of one specially prepared extract of adrenal cortex containing compounds E (cortisone) and F produced appreciable relief in 1 case of rheumatoid arthritis and has lent support to the belief that cortisone, and perhaps also compound F, will be chemically effective when given orally.

The mode of action of cortisone and pituitary adrenocorticotropic hormone in rheumatic diseases is not yet known, but the hormones appear to provide to the tissues affected in these diseases a shieldlike buffer against a variety of irritants.

The results of recent and current investigative studies appear to provide justification for the impending restricted application of these hormones to the field of therapy, at least in certain acute rheumatic and articular conditions.

EFFECT OF PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) ON RHEUMATIC FEVER AND RHEUMATIC CARDITIS

BENEDICT F. MASSELL, M.D.
and
JOSEPH E. WARREN, M.D.
Boston

That cortisone and pituitary adrenocorticotropic hormone (ACTH) might be useful in the treatment of rheumatic fever was first suggested by Hench and his co-workers[1] in May, 1949, shortly after they had announced their observations on the remarkable effects of these hormones in rheumatoid arthritis.[2] Although more than a year has now elapsed, published data on the effects of these hormones on the clinical course of rheumatic fever are still limited.

Hench's original report[1] included three rheumatic fever patients treated at the Mayo Clinic with cortisone for periods of 21 to 37 days and one patient who had received pituitary adrenocorticotropic hormone for seven days at the time that the report was prepared. More recent publications from the Mayo Clinic[3] have included data on these same cases as well as on four additional cortisone-treated patients and three additional ACTH-treated patients. Elkinton and others[4] administered the latter agent to two patients with rheumatic fever but discontinued the hormone after only three days of treatment. McEwen and his associates[5] reported observations on three patients, one of whom was treated with pituitary adrenocorticotropic hormone alone and two of whom were treated with cortisone first and then with the other hormone. Therapy was continued for periods totaling 30 to 45 days. In a recent article, Thorn and co-workers[6] described the apparent response of a girl with severe rheumatic fever to pituitary adrenocorticotropic hormone administered for a total of only 72 hours.

Preliminary reports of our own experience with this hormone in rheumatic fever have already been published.[7] One of these reports,[7c] which includes detailed case histories of the first 10 patients, covers the period from May 17 to Oct. 23, 1949. During the interval which has elapsed from the latter date to the preparation of this more current report (June 10, 1950), 10 additional patients with definite rheumatic fever[8] have received pituitary adrenocorticotropic hormone therapy at the House of the Good Samaritan. The purpose of the present communication is to summarize our clinical observations on the entire series of 20 patients so treated.

CLINICAL MATERIAL AND METHOD OF TREATMENT

The manifestations of rheumatic fever and carditis present in each of the 20 patients at the time pituitary adrenocorticotropic hormone therapy was begun are indicated in table 1. The duration of the rheumatic attack prior to the beginning of hormone treatment, the number of previous attacks of rheumatic fever, and the age and sex of the patients are summarized in table 2. It is evident from these data that nearly all of the important manifestations of rheumatic fever are represented by this clinical series and that the majority of the patients had severe rheumatic fever and a high degree of active rheumatic carditis.

To obtain information regarding the optimum method of applying pituitary adrenocorticotropic hormone[9] to the treatment of rheumatic fever, various dosage schedules have been tried. These variations in therapy include amount of drug in each individual dose, total daily amount, number of doses per day, number of days of treatment, and total amount administered throughout the period of therapy. In the majority of the patients the total daily dose of the hormone was gradually reduced as treatment progressed, but in some cases the daily amount was kept constant. Some of the more pertinent data relevant to treatment are summarized in table 3.

Read in the Symposium on ACTH and Cortisone before the Section on Experimental Medicine and Therapeutics at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 28, 1950.

[9] The pituitary adrenocorticotropic hormone used in these studi[illegible] supplied by Dr. John R. Mote of the Armour Laboratories, [illegible] All doses are recorded in terms of milligrams of the Armour [illegible]

plans have the supposed advantage of plan 2 plus the theoretical possibility that a more nearly balanced and perhaps more effective cortical secretion might be provided. The value of these last two plans (5 and 6) remains to be proved.

Augmented Administration.—Certain workers have expressed the hope that some substance (gold salts, salicylates, vitamin C or other steroid) might be found which would augment or enhance the effect of doses of cortisone or pituitary adrenocorticotropic hormone which were so small that no side effects would develop. Our experience with salicylates and vitamin C given during courses of these hormones has been disappointing; no potentiation of cortisone was observed.

METHODS OF WITHDRAWAL

Sudden withdrawal of either hormone may be followed by a relatively short period of annoying weakness, occasionally by a "rebound relapse" of articular symptoms. These phenomena are presumably due to the temporary inhibition of adrenal cortex function which use of the exogenous hormones induces. This posthormonal period of relative adrenocortical insufficiency disappears fairly soon. To minimize it two methods of withdrawal have been suggested: (1) to taper off the daily doses of either of the hormones, giving successively smaller doses the last few (seven to 10) days and (2) to conclude a course of cortisone by giving pituitary adrenocorticotropic hormone for a few days.

PREVENTION AND CONTROL OF SIDE EFFECTS

When the prolonged use of cortisone or pituitary adrenocorticotropic hormone appears necessary (for example, in the investigative management of rheumatoid arthritis) the following procedures will help to prevent, minimize or counteract adverse side effects. When the early suppressive doses have brought the symptoms of the disease largely under control, as soon as possible the smallest effective maintenance doses should be used. Suppression of subjective symptoms, and not necessarily normalization of sedimentation rates also, should be considered sufficient. If the doses needed for full symptomatic relief begin to produce significant side effects, the dosage should be reduced and physician and patient alike should be content with less than full suppression of the disease.

If significant edema develops or persists, a reduced intake of sodium chloride (1 Gm. or less daily for adults) or the oral use of a diuretic such as potassium nitrate (2 Gm. or more three times a day) or both may suffice. For one menopausal woman [1] the administration of estrogen, 5 mg. twice a week, during a second course of cortisone prevented the development of several side effects (among them round face, hypertrichosis and nervousness) which had occurred during the first course. Further studies with estrogen are being made. Significant imbalance of electrolytes will not often occur when the daily doses of cortisone are 100 mg. or less, of pituitary adrenocorticotropic hormone 40 mg. or less, and especially when patients are eating at will rather than having dietary restrictions incident to metabolic studies. If hypopotassemic, hypochloremic alkalosis does occur (with or without muscular weakness, hypertension and electrocardiographic alterations) the oral administration of potassium chloride, 1 or 2 Gm. three times a day, is indicated. Significant nitrogen deficits will probably not develop in the rheumatoid patients who are on unrestricted diets and who are not receiving the larger doses of the hormones. If significant loss of weight and weakness should develop, an increased intake of nitrogen will probably suffice. Testosterone propionate, 25 mg. given intramuscularly daily, in 1 case prevented the nitrogen deficit produced by large doses of cortisone.[5] Testosterone propionate can be given sublingually.

The minor alterations of psyche (grades 1 and 2) need no treatment. The changes described as a grade 3 response may require the establishment of a psychological regimen comparable to that which would be needed to manage the same kind of reaction in other clinical settings. Such adjuncts as sedation, a fixed schedule of activities and the opportunity to discuss basic psychological difficulties can provide a support which may make the continuation of hormonal usage possible. Cessation of hormonal therapy removes the provocative component. Obviously the treatment of the fundamental psychiatric problem needs a special approach. In our experience a frank psychotic response (grade 4) is infrequent and is only likely to occur in patients who are psychologically vulnerable. The hormones should be used with caution for patients with previous history of a psychosis or other evidence of pronounced instability. The management of a hormonally precipitated psychotic episode requires specifically indicated measures to control the response, including the withdrawal of the hormone.[6] Measures to prevent or control postcortisone weakness have been mentioned under "Methods of Withdrawal."

SUMMARY AND CONCLUSIONS

The antirheumatic properties of cortisone and pituitary adrenocorticotropic hormone (ACTH) have been confirmed by several groups of investigators.

During the time of their administration, these hormones have exerted a decidedly suppressive effect on the clinical and biochemical manifestations of rheumatoid arthritis. When the use of the hormones is discontinued symptoms recur rather promptly in most cases, but in several of our cases pronounced improvement has persisted for several (seven to 14) months. The optimal dosage and methods of administration of these hormones for the investigative management of a chronic disease such as rheumatoid arthritis remain to be determined. Several schemes are under investigation. Rather prolonged relief with minimal side effects has been provided in some cases by the continued use of small maintenance doses after the earlier use of larger suppressive doses.

Cortisone or pituitary adrenocorticotropic hormone generally abolishes quickly the manifestations of acute rheumatic fever. There is reason to believe that the lesions of acute rheumatic carditis also are suppressed, in consequence of which the prevention of certain chronic cardiac lesions may be anticipated with some confidence, especially if adequate hormonal usage during the acute rheumatic state is followed by prolonged chemoprophylaxis (for example, with penicillin given orally). The articular complications of disseminated lupus erythematosus and psoriasis are responsive to these hormones. Limited results were obtained in 2 cases of tuberculous arthritis.

These hormones are powerful agents which may affect many functions and tissues of the body besides those of joints and muscles. Their prolonged use, at least in certain doses, may produce certain undesirable effects. These side effects have, to date, been transient and reversible. Certain measures have been developed to minimize or control some of them, but these effects still constitute an important problem for further investigation. If control of the side effects is not adequate in any given case, smaller doses of the hormones should be used and patient and physician alike should be content with a reduced amount of symptomatic relief.

With the exception of 17-hydroxycorticosterone (compound F of Kendall), none of the currently available steroids chemically related to cortisone appears to have significant antirheumatic properties. The oral administration of one specially prepared extract of adrenal cortex containing compounds E (cortisone) and F produced appreciable relief in 1 case of rheumatoid arthritis and has lent support to the belief that cortisone, and perhaps also compound F, will be chemically effective when given orally.

The mode of action of cortisone and pituitary adrenocorticotropic hormone in rheumatic diseases is not yet known, but the hormones appear to provide to the tissues affected in these diseases a shieldlike buffer against a variety of irritants.

The results of recent and current investigative studies appear to provide justification for the impending restricted application of these hormones to the field of therapy, at least in certain acute rheumatic and articular conditions.

EFFECT OF PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) ON RHEUMATIC FEVER AND RHEUMATIC CARDITIS

BENEDICT F. MASSELL, M D
and
JOSEPH E. WARREN, M D
Boston

That cortisone and pituitary adrenocorticotropic hormone (ACTH) might be useful in the treatment of rheumatic fever was first suggested by Hench and his co-workers[1] in May, 1949, shortly after they had announced their observations on the remarkable effects of these hormones in rheumatoid arthritis.[2] Although more than a year has now elapsed, published data on the effects of these hormones on the clinical course of rheumatic fever are still limited.

Hench's original report[1] included three rheumatic fever patients treated at the Mayo Clinic with cortisone for periods of 21 to 37 days and one patient who had received pituitary adrenocorticotropic hormone for seven days at the time that the report was prepared. More recent publications from the Mayo Clinic[3] have included data on these same cases as well as on four additional cortisone-treated patients and three additional ACTH-treated patients. Elkinton and others[4] administered the latter agent to two patients with rheumatic fever but discontinued the hormone after only three days of treatment. McEwen and his associates[5] reported observations on three patients, one of whom was treated with pituitary adrenocorticotropic hormone alone and two of whom were treated with cortisone first and then with the other hormone. Therapy was continued for periods totaling 30 to 45 days. In a recent article, Thorn and co-workers[6] described the apparent response of a girl with severe rheumatic fever to pituitary adrenocorticotropic hormone administered for a total of only 72 hours.

Preliminary reports of our own experience with this hormone in rheumatic fever have already been published.[7] One of these reports,[7c] which includes detailed case histories of the first 10 patients, covers the period from May 17 to Oct. 23, 1949. During the interval which has elapsed from the latter date to the preparation of this more current report (June 10, 1950), 10 additional patients with definite rheumatic fever[8] have received pituitary adrenocorticotropic hormone therapy at the House of the Good Samaritan. The purpose of the present communication is to summarize our clinical observations on the entire series of 20 patients so treated

CLINICAL MATERIAL AND METHOD OF TREATMENT

The manifestations of rheumatic fever and carditis present in each of the 20 patients at the time pituitary adrenocorticotropic hormone therapy was begun are indicated in table 1. The duration of the rheumatic attack prior to the beginning of hormone treatment, the number of previous attacks of rheumatic fever, and the age and sex of the patients are summarized in table 2. It is evident from these data that nearly all of the important manifestations of rheumatic fever are represented by this clinical series and that the majority of the patients had severe rheumatic fever and a high degree of active rheumatic carditis.

To obtain information regarding the optimum method of applying pituitary adrenocorticotropic hormone[9] to the treatment of rheumatic fever, various dosage schedules have been tried. These variations in therapy include amount of drug in each individual dose, total daily amount, number of doses per day, number of days of treatment, and total amount administered throughout the period of therapy. In the majority of the patients the total daily dose of the hormone was gradually reduced as treatment progressed, but in some cases the daily amount was kept constant. Some of the more pertinent data relevant to treatment are summarized in table 3.

[8] Not included in this group is one patient with possibly complicating bronchiectasis and several patients in whom the clinical course has not sufficiently progressed for adequate evaluation.

[9] The pituitary adrenocorticotropic hormone used in these study supplied by Dr. John R. Mote of the Armour Laboratories, All doses are recorded in terms of milligrams of the Armour

To facilitate the collection of data needed for studies on the mechanism of hormonal influences in rheumatic fever, nearly all of the patients treated with pituitary adrenocorticotropic hormone were placed on a metabolic balance diet containing an average of 0.6 Gm. of sodium per day. In addition to the usual clinical observations, the study has been controlled by a variety of laboratory tests which have been described elsewhere.[7c]

Treatment is still being given to one patient (case 20) and was only recently discontinued in another (case 19). In the remaining 18 cases the period of follow-up since discontinuation of hormonal therapy has varied from seven weeks to 12 months.

INITIAL RESPONSE OF VARIOUS MANIFESTATIONS

The number of days after the beginning of pituitary adrenocorticotropic hormone therapy for the more important symptoms and signs of rheumatic fever to disappear in each of the 20 patients is indicated in table 4. Attention should be called to the fact that the figures in the table refer to the time for initial disappearance. Certain rheumatic manifestations reappeared in some cases usually when the agent was reduced in dosage or entirely omitted. This aspect of the problem is discussed below more fully. An instance of what is considered to be a good response to pituitary adrenocorticotropic hormone is illustrated by figure 1.

It is evident from the data in table 4 that of all symptoms and signs fever and polyarthritis came under control most rapidly. In most instances these two manifestations subsided within one or two days of therapy. Pericarditis usually became appreciably diminished or disappeared entirely within three to four days of hormonal treatment, but in three patients (cases 5, 9 and 16) nine to 14 days were required for complete subsidence. With regard to the response in case 9, it should be pointed out that after the first five days of therapy exhaustion of our supply of hormone necessitated discontinuing treatment temporarily during the succeeding five days.

In 4 of 5 patients with subcutaneous nodules the lesions became detectably smaller within seven to 10 days of the beginning of therapy and appeared to be totally absent by the end of two to seven weeks of treatment. In one patient (case 3) the nodules became smaller gradually and did not entirely disappear until about three weeks after termination of therapy. Furthermore, new nodules appeared shortly afterward on both forearms distal to the olecranon processes.

The erythrocyte sedimentation rate usually became significantly slower after one to five days of treatment and in the majority of patients reached a normal level within one to three weeks. In 4 patients (cases 5, 7, 15 and 17) the response was slower, and one to three months of therapy elapsed before normal readings were observed.

Only 2 of the patients in this series (cases 8 and 19) had chorea. In the first of these improvement during therapy was quite striking. Although the hormone was given for a total of only 10 days, at the end of this period the chorea, which had been moderately severe prior to treatment, had become mild. Thereafter and without further therapy the slight residual chorea gradually lessened and within another three weeks completely disappeared. The second patient, recently admitted to the hospital, had moderately severe chorea of nearly one month's duration. After 10 days of therapy with relatively large doses of the hormone, the chorea was no less severe than it had been before this treatment; therefore, in order to determine whether withdrawal of the hormone would have any influence on the choreiform motions, treatment was discontinued. It is too soon to evaluate the effect of this procedure.

* Figures refer to the number of days required for initial disappearance of manifestations; certain of these reappeared later. Instances in which subsidence of manifestation was not clearly associated with therapy are omitted.

† Manifestation did not completely subside during the period of observation.

Improvement in appetite and gain in weight with pituitary adrenocorticotropic hormone therapy was frequently impressive and was often remarkably prompt. Disappearance of moderate anemia in association with other signs of improvement was likewise noticeable in a number of cases. In several patients who had a decided sinus tachycardia there was considerable slowing of the heart rate soon after treatment was begun. In addition the hormone may also have played a role in the improvement of one patient with paroxysmal auricular tachycardia (case 11).

The influence of pituitary adrenocorticotropic hormone on congestive heart failure was somewhat variable; therefore it can best be described by considering separately each of the 6 patients in whom this manifestation of active carditis was present.

CASE 2.—A woman aged 21 had severe heart damage as the result of long-standing repetitive rheumatic fever. She had been on a maintenance dose of digitalis for some time. With her most recent rheumatic recurrence there developed severe congestion of the liver and sacral edema which failed to respond to a low sodium diet and frequent administration of a mercurial diuretic. During the first week of pituitary adrenocorticotropic hormone therapy the signs of congestion lessened slightly. Then, with temporary omission of hormone therapy for a period of three days (due to exhaustion of our supply) there was a decided diuresis accompanied with further striking improvement in the signs of congestive failure. When hormone therapy was resumed a satisfactory urinary output was maintained, and improvement continued so that by the fourteenth day after the initial dose of pituitary adrenocorticotropic hormone signs of congestive failure could not longer be detected. Thereafter the patient was able to get along well without the further administration of diuretics. Some of the pertinent features of this patient's clinical response to the hormone, including the urinary excretion of sodium, are illustrated in figure 2.

To facilitate the collection of data needed for studies on the mechanism of hormonal influences in rheumatic fever, nearly all of the patients treated with pituitary adrenocorticotropic hormone were placed on a metabolic balance diet containing an average of 0.6 Gm. of sodium per day. In addition to the usual clinical observations, the study has been controlled by a variety of laboratory tests which have been described elsewhere.[7c]

Treatment is still being given to one patient (case 20) and was only recently discontinued in another (case 19). In the remaining 18 cases the period of follow-up since discontinuation of hormonal therapy has varied from seven weeks to 12 months.

INITIAL RESPONSE OF VARIOUS MANIFESTATIONS

The number of days after the beginning of pituitary adrenocorticotropic hormone therapy for the more important symptoms and signs of rheumatic fever to disappear in each of the 20 patients is indicated in table 4. Attention should be called to the fact that the figures in the table refer to the time for initial disappearance. Certain rheumatic manifestations reappeared in some cases usually when the agent was reduced in dosage or entirely omitted. This aspect of the problem is discussed below more fully. An instance of what is considered to be a good response to pituitary adrenocorticotropic hormone is illustrated by figure 1.

It is evident from the data in table 4 that of all symptoms and signs fever and polyarthritis came under control most rapidly. In most instances these two manifestations subsided within one or two days of therapy. Pericarditis usually became appreciably diminished or disappeared entirely within three to four days of hormonal treatment, but in three patients (cases 5, 9 and 16) nine to 14 days were required for complete subsidence. With regard to the response in case 9, it should be pointed out that after the first five days of therapy exhaustion of our supply of hormone necessitated discontinuing treatment temporarily during the succeeding five days.

In 4 of 5 patients with subcutaneous nodules the lesions became detectably smaller within seven to 10 days of the beginning of therapy and appeared to be totally absent by the end of two to seven weeks of treatment. In one patient (case 3) the nodules became smaller gradually and did not entirely disappear until about three weeks after termination of therapy. Furthermore, new nodules appeared shortly afterward on both forearms distal to the olecranon processes.

The erythrocyte sedimentation rate usually became significantly slower after one to five days of treatment and in the majority of patients reached a normal level within one to three weeks. In 4 patients (cases 5, 7, 15 and 17) the response was slower, and one to three months of therapy elapsed before normal readings were observed.

Only 2 of the patients in this series (cases 8 and 19) had chorea. In the first of these improvement during therapy was quite striking. Although the hormone was given for a total of only 10 days, at the end of this period the chorea, which had been moderately severe prior to treatment, had become mild. Thereafter and without further therapy the slight residual chorea gradually lessened and within another three weeks completely disappeared. The second patient, recently admitted to the hospital, had moderately severe chorea of nearly one month's duration. After 10 days of therapy with relatively large doses of the hormone, the chorea was no less severe than it had been before this treatment; therefore, in order to determine whether withdrawal of the hormone would have any influence on the choreiform motions, treatment was discontinued. It is too soon to evaluate the effect of this procedure.

Improvement in appetite and gain in weight with pituitary adrenocorticotropic hormone therapy was frequently impressive and was often remarkably prompt. Disappearance of moderate anemia in association with other signs of improvement was likewise noticeable in a number of cases. In several patients who had a decided sinus tachycardia there was considerable slowing of the heart rate soon after treatment was begun. In addition the hormone may also have played a role in the improvement of one patient with paroxysmal auricular tachycardia (case 11).

The influence of pituitary adrenocorticotropic hormone on congestive heart failure was somewhat variable; therefore it can best be described by considering separately each of the 6 patients in whom this manifestation of active carditis was present.

CASE 2.—A woman aged 21 had severe heart damage as the result of long-standing repetitive rheumatic fever. She had been on a maintenance dose of digitalis for some time. With her most recent rheumatic recurrence there developed severe congestion of the liver and sacral edema which failed to respond to a low sodium diet and frequent administration of a mercurial diuretic. During the first week of pituitary adrenocorticotropic hormone therapy the signs of congestion lessened slightly. Then, with temporary omission of hormone therapy for a period of three days (due to exhaustion of our supply) there was a decided diuresis accompanied with further striking improvement in the signs of congestive failure. When hormone therapy was resumed a satisfactory urinary output was maintained, and improvement continued so that by the fourteenth day after the initial dose of pituitary adrenocorticotropic hormone signs of congestive failure could not longer be detected. Thereafter the patient was able to get along well without the further administration of diuretics. Some of the pertinent features of this patient's clinical response to the hormone, including the urinary excretion of sodium, are illustrated in figure 2.

* Figures refer to the number of days required for initial disappearance of manifestations; certain of these reappeared later. Instances in which subsidence of manifestation was not clearly associated with therapy are omitted.

† Manifestation did not completely subside during the period of observation.

Case 3.—A girl 7 years of age had severe rheumatic carditis and congestive failure, the latter condition being indicated by the presence of a gallop rhythm, an enlarged tender liver, cough and orthopnea. Prior to the administration of pituitary adrenocorticotropic hormone the patient had been on a low sodium diet but had not received other cardiac therapy. During the first three days of hormone treatment the signs of congestion of the liver and lungs increased to such an extent that a daily mercurial diuretic was added to the therapeutic regimen. Thereafter the signs of congestion lessened considerably, so that three weeks after the beginning of hormone treatment the only residual sign possibly indicative of congestive failure was a liver edge palpable just slightly below the costal margin. Furthermore, administration of the mercurial diuretic was omitted two weeks later without the development of any increase in the signs of congestion.

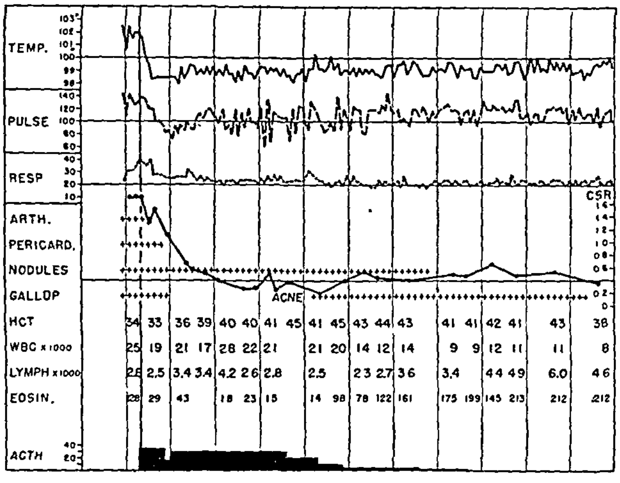

Fig. 1 (case 1).—Chart showing clinical response of patient to pituitary adrenocorticotropic hormone (ACTH) therapy. Light vertical lines indicate weekly intervals. The heavy vertical line indicates the beginning of therapy. Note transient rise in sedimentation rate when the hormone was reduced to low dosage. In column at left HCT indicates the hematocrit level.

Case 5.—A girl 8 years of age had severe rheumatic carditis and pronounced congestion of the liver. In spite of a low sodium diet the first four days of pituitary adrenocorticotropic hormone therapy were accompanied with an increase in hepatic congestion and a decided increase in the respiratory rate. With the daily administration of a mercurial diuretic the signs of congestive failure regressed, and one month after the first injection of the hormone the patient was sufficiently improved to allow discontinuation of diuretic therapy. Although slight liver enlargement persisted, there was no doubt that the signs of congestion were considerably improved in comparison to those present prior to hormone treatment.

Case 10.—A boy aged 17 had severe active rheumatic fever, long-standing rheumatic heart disease and auricular fibrillation. Prior to pituitary adrenocorticotropic hormone therapy, in spite of full digitalization, he was in severe congestive failure with hepatic enlargement. Digitalis was withheld, and on the sixth hospital day hormone therapy was begun. By the eighteenth hospital day (twelfth day of the hormone) the heart rate had increased to 150 beats per minute; the liver had become larger and was quite tender; there was slight sacral edema, and the patient was obviously orthopneic. Consequently the patient was rapidly redigitalized by the intravenous route with crystalline lanatoside C. This therapeutic procedure was followed by a prompt slowing of the heart rate and a rapid disappearance of all signs of congestion. Furthermore, with a maintenance oral dose of digitoxin the heart rate remained well controlled and there was no recurrence of congestive failure.

Case 13.—A boy 8 years of age had active rheumatic fever of six months' duration and chronic hepatic congestion of at least three and one half months' duration. With pituitary adrenocorticotropic hormone and diuretic therapy the size of his liver diminished somewhat but nevertheless continued to remain obviously enlarged. Furthermore, the patient finally died after three months of hormone treatment as the result of bilateral thrombophlebitis of the internal jugular vein, and autopsy revealed the presence of chronic passive congestion of the liver.

Case 18.—A girl aged 17 had smoldering active rheumatic fever which had persisted ever since her third frank attack of acute rheumatic fever three and one half years previously. Increasing sinus tachycardia, development of frequent attacks of paroxysmal auricular tachycardia and enlargement of the liver gave evidence of progressive cardiac damage. With pituitary adrenocorticotropic hormone therapy the signs of hepatic congestion increased, but the situation was reasonably well controlled by the use of diuretics and a low sodium diet. After the discontinuation of hormone therapy, even though a low sodium diet and frequent administration of diuretics were continued, definite signs of hepatic congestion persisted.

The final rheumatic manifestation to be considered is the auscultatory signs of heart disease. Such signs were present in 18 of the 20 patients in this series. In most instances the significant murmurs were due to long-standing valvular damage, and, as might be expected, they were not influenced by pituitary adrenocorticotropic hormone therapy. But in 5 cases significant murmurs, which presumably were of relatively recent origin, regressed in association with other clinical signs of improvement and finally disappeared completely within several weeks to several months. The auscultatory signs which disappeared included a moderately loud mitral systolic murmur in one instance, mitral middiastolic murmurs in three instances and faint to moderately intense aortic diastolic murmurs in four instances. In spite of the disappearance of some murmurs, other murmurs have given ample evidence of persistent heart disease in three of the five patients (cases 4, 14 and 15). However, two of the five patients (cases 1 and 7), during a follow-up period of about 11 months, have remained entirely free of signs of residual cardiac damage.

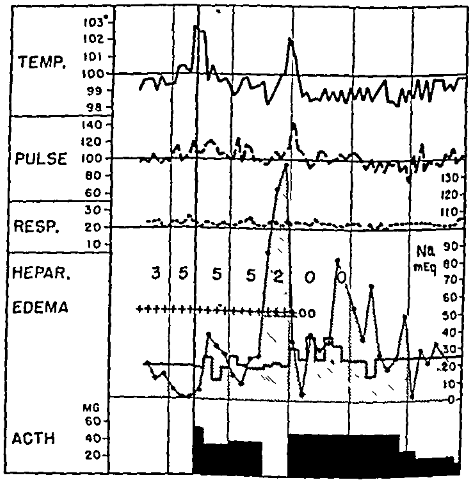

Fig. 2 (case 2).—Chart showing effect of pituitary adrenocorticotropic hormone in a patient with congestive failure. The patient was on a constant regimen of digitoxin 0.1 mg. and a mercurial diuretic 1 cc. per day. Light vertical lines indicate weekly intervals. The heavy vertical line indicates the beginning of therapy. The shaded area indicates urinary excretion of sodium in milliequivalents per day. The heavy line through the shaded area [illegible] per day. Note the rise in temperature and the [illegible] when the hormone was temporarily discontinued after eight days of therapy.

WITHDRAWAL EFFECTS

When pituitary adrenocorticotropic hormone was withdrawn abruptly early in the course of treatment of patients with acute rheumatic fever an almost immediate rise in temperature and return of symptoms occurred, a result that was not surprising. Of possibly greater significance was the reaction to gradual reduction in dosage and final omission of therapy. In some instances the procedure was not associated with any untoward effect. In others, however, relapses of varying severity were observed. The interesting feature of these late withdrawal reactions is that in a number of instances fever, joint pains and rise in sedimentation rate again subsided and failed to reappear even though the reduced hormone dosage was kept constant or the hormone was omitted altogether. As might be expected, elevation of the sedimentation rate subsided more slowly than did the clinical manifestations of these withdrawal reactions. In general, clinical withdrawal symptoms lasted for only three to 10 days, but rebound elevation of the sedimentation rate did not subside entirely for periods varying from one week to three months. A withdrawal reaction involving only the sedimentation rate is illustrated in figure 1.

The effect of withdrawing pituitary adrenocorticotropic hormone in one patient (case 18) is of especial interest and worthy of further consideration. This patient is the girl aged 17 to whom reference has already been made in connection with the effect of the hormone on congestive heart failure. She had had persistent smoldering active rheumatic fever for about three and one half years prior to therapy, but during this period she did not have any fever. When after seven weeks of treatment the dose was reduced to 10 mg. per day and a little later omitted entirely, fever developed with the patient's oral temperatures reaching as high as 103.5 F. During the next 10 weeks fever persisted except for varying intervals when the patient was treated with aspirin (acetylsalicylic acid), ascorbic acid in large doses or more pituitary adrenocorticotropic hormone. All antirheumatic therapy was finally omitted a little over two weeks ago, and so far the temperature has remained normal. A careful search has been made for possible causes for the fever, unrelated to rheumatic fever, but so far none has been found; therefore it seems quite possible, in spite of the lack of other obviously rheumatic manifestations, that the febrile withdrawal reaction in this patient represents a recrudescence of rheumatic fever.

UNTOWARD REACTIONS

From the previous discussion of the effect of pituitary adrenocorticotropic hormone on congestive heart failure it is evident that in a number of instances this condition was aggravated during the early period of hormone therapy. The tendency of the drug to cause water retention may in turn be due to its sodium-retaining effect or in part to a direct effect on the kidneys of contaminating antidiuretic principles in the hormonal preparation. Whatever the cause, the effect constitutes a distinct risk for the patient with severe carditis. Fortunately in our patients aggravation of congestive failure was adequately controlled by the use of diuretics and a diet exceedingly low in sodium.

The only other serious untoward reaction which can be reasonably attributed to pituitary adrenocorticotropic hormone therapy in this series of 20 patients is a single instance of severe mental depression. This latter condition developed in a woman aged 21 (case 2) after treatment for about one month but disappeared again one month after discontinuation of hormone treatment.

One patient with severe active carditis and chronic congestive failure (case 13) was treated with the hormone in gradually reduced dosage for about three months. Toward the end of this period, while he was receiving only 4 mg. per day, there developed bilateral thrombophlebitis of the internal jugular veins and he died shortly thereafter. Although the possibility must be considered that the hormone may have played a role in the development of this fatal complication, other contributory factors to be considered are active rheumatic fever, congestive failure with venous stasis and the mercurial diuretic which was administered frequently in an attempt to combat the congestive failure.

Other relatively minor side effects from pituitary adrenocorticotropic hormone were transient headache in two cases, slight striae in two cases, acne in seven cases and development of varying degrees of roundness of the face in eight cases. The latter two manifestations usually became apparent during the second to fourth week of treatment and lessened gradually after discontinuation of therapy. In eight patients there developed no side reactions whatsoever. Significant elevation of the blood sugar level, glycosuria and hypertension were not observed in any of the 20 patients of this series.

THERAPEUTIC WORTH OF THE HORMONE

The prompt reduction in fever, the rapid disappearance of joint symptoms and the other immediate effects of pituitary adrenocorticotropic hormone therapy (indicated in table 4) which have already been discussed are extremely impressive. It must be pointed out, however, that the assessment of antirheumatic agents should not be based on immediate effects alone. If a drug is to have real value in the treatment of rheumatic fever it must do one or more of the following things: (1) shorten the course of the attack of rheumatic fever; (2) suppress active carditis, and (3) prevent or reduce residual cardiac damage.

Data relative to duration of the observed attacks of rheumatic fever in the first 19 patients of this series in whom hormone therapy has been completed are presented in table 2. The attacks were not considered to have been terminated until the effects of the withdrawal reactions, in those cases in which such reactions occurred, also subsided. Duration of active rheumatic fever is recorded in the table in two ways: (1) duration of clinical manifestations without regard to laboratory observations, and (2) total duration of rheumatic activity based on both clinical and laboratory results, especially the erythrocyte sedimentation rate.

One patient (case 19) with moderately severe chorea failed to show any improvement after ten days of therapy with large doses of pituitary adrenocorticotropic hormone. Another patient (case 13) died of a complicating jugular thrombophlebitis after about three months of therapy. A third patient (case 18) with previous persistent low grade rheumatic fever has continued to have active rheumatic fever in spite of therapy. As has already been indicated in a previous discussion, it is even possible in this case that the rheumatic process has actually increased in severity since discontinuation of the course of pituitary adrenocorticotropic hormone. A fourth patient (case 3), although finally recovered from rheumatic fever, must be considered a therapeutic failure because she did not seem to improve during the period of hormone treatment.

Of the remaining 15 patients final clinical recovery was observed in five patients within only one week of hormone therapy, in six patients within two to four weeks after the beginning of treatment and in four patients not until six to eight weeks after the first injection of the hormone. If the analysis is done on the basis of laboratory tests, particularly the erythrocyte

Case 3.—A girl 7 years of age had severe rheumatic carditis and congestive failure, the latter condition being indicated by the presence of a gallop rhythm, an enlarged tender liver, cough and orthopnea. Prior to the administration of pituitary adrenocorticotropic hormone the patient had been on a low sodium diet but had not received other cardiac therapy. During the first three days of hormone treatment the signs of congestion of the liver and lungs increased to such an extent that a daily mercurial diuretic was added to the therapeutic regimen. Thereafter the signs of congestion lessened considerably, so that three weeks after the beginning of hormone treatment the only residual sign possibly indicative of congestive failure was a liver edge palpable just slightly below the costal margin. Furthermore, administration of the mercurial diuretic was omitted two weeks later without the development of any increase in the signs of congestion.

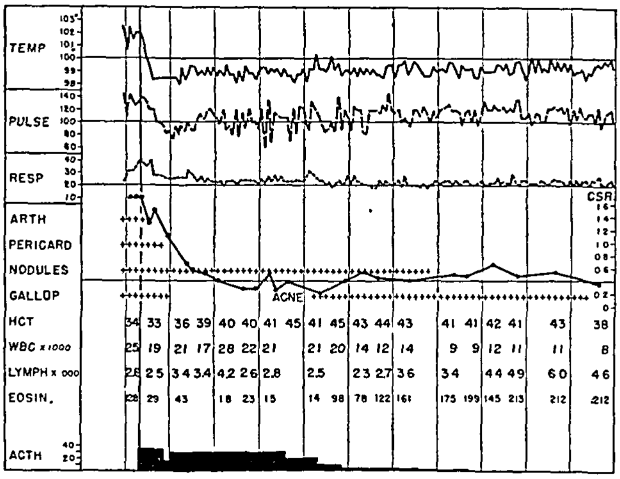

Fig 1 (case 1).—Chart showing clinical response of patient to pituitary adrenocorticotropic hormone (ACTH) therapy. Light vertical lines indicate weekly intervals The heavy vertical line indicates the beginning of therapy. Note transient rise in sedimentation rate when the hormone was reduced to low dosage. In column at left HCT indicates the hematocrit level

Case 5.—A girl 8 years of age had severe rheumatic carditis and pronounced congestion of the liver. In spite of a low sodium diet the first four days of pituitary adrenocorticotropic hormone therapy were accompanied with an increase in hepatic congestion and a decided increase in the respiratory rate. With the daily administration of a mercurial diuretic the signs of congestive failure regressed, and one month after the first injection of the hormone the patient was sufficiently improved to allow discontinuation of diuretic therapy. Although slight liver enlargement persisted, there was no doubt that the signs of congestion were considerably improved in comparison to those present prior to hormone treatment.

Case 10.—A boy aged 17 had severe active rheumatic fever, long-standing rheumatic heart disease and auricular fibrillation Prior to pituitary adrenocorticotropic hormone therapy, in spite of full digitalization, he was in severe congestive failure with hepatic enlargement. Digitalis was withheld, and on the sixth hospital day hormone therapy was begun. By the eighteenth hospital day (twelfth day of the hormone) the heart rate had increased to 150 beats per minute; the liver had become larger and was quite tender; there was slight sacral edema, and the patient was obviously orthopneic. Consequently the patient was rapidly redigitalized by the intravenous route with crystalline lanatoside C. This therapeutic procedure was followed by a prompt slowing of the heart rate and a rapid disappearance of all signs of congestion. Furthermore, with a maintenance oral dose of digitoxin the heart rate remained well controlled and there was no recurrence of congestive failure.

Case 13.—A boy 8 years of age had active rheumatic fever of six months' duration and chronic hepatic congestion of at least three and one half months' duration. With pituitary adrenocorticotropic hormone and diuretic therapy the size of his liver diminished somewhat but nevertheless continued to remain obviously enlarged. Furthermore, the patient finally died after three months of hormone treatment as the result of bilateral thrombophlebitis of the internal jugular vein, and autopsy revealed the presence of chronic passive congestion of the liver.

Case 18.—A girl aged 17 had smoldering active rheumatic fever which had persisted ever since her third frank attack of acute rheumatic fever three and one half years previously Increasing sinus tachycardia, development of frequent attacks of paroxysmal auricular tachycardia and enlargement of the liver gave evidence of progressive cardiac damage With pituitary adrenocorticotropic hormone therapy the signs of hepatic congestion increased, but the situation was reasonably well controlled by the use of diuretics and a low sodium diet After the discontinuation of hormone therapy, even though a low sodium diet and frequent administration of diuretics were continued, definite signs of hepatic congestion persisted

The final rheumatic manifestation to be considered is the auscultatory signs of heart disease. Such signs were present in 18 of the 20 patients in this series In most instances the significant murmurs were due to long-standing valvular damage, and, as might be expected, they were not influenced by pituitary adrenocorticotropic hormone therapy. But in 5 cases significant murmurs, which presumably were of relatively recent origin, regressed in association with other clinical signs of improvement and finally disappeared completely within several weeks to several months. The auscultatory signs which disappeared included a moderately loud mitral systolic murmur in one instance, mitral middiastolic murmurs in three instances and faint to moderately intense aortic diastolic murmurs in four instances. In spite of the disappearance of some murmurs, other murmurs have given ample evidence of persistent heart disease in three of the five patients (cases 4, 14 and 15). However, two of the five patients (cases 1 and 7), during a follow-up period of about 11 months, have remained entirely free of signs of residual cardiac damage.

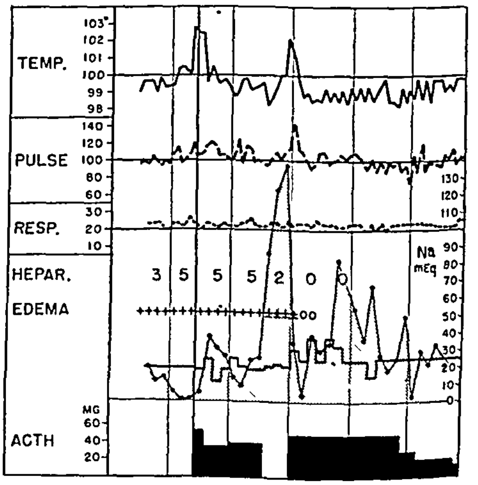

Fig 2 (case 2).—Chart showing effect of pituitary adrenocorticotropic hormone in a patient with congestive failure The patient was on a constant regimen of digitoxin 0.1 mg and a mercurial diuretic 1 cc per day Light vertical lines indicate weekly intervals. The heavy vertical line indicates the beginning of therapy. The shaded area indicates urinary excretion of sodium in milliequivalents per day. The heavy line through the shaded area indicates sodium intake per day. Note the rise in temperature and the decided sodium diuresis when the hormone was temporarily discontinued after eight days of therapy.

WITHDRAWAL EFFECTS

When pituitary adrenocorticotropic hormone was withdrawn abruptly early in the course of treatment of patients with acute rheumatic fever an almost immediate rise in temperature and return of symptoms occurred, a result that was not surprising. Of possibly greater significance was the reaction to gradual reduction in dosage and final omission of therapy. In some instances the procedure was not associated with any untoward effect. In others, however, relapses of varying severity were observed. The interesting feature of these late withdrawal reactions is that in a number of instances fever, joint pains and rise in sedimentation rate again subsided and failed to reappear even though the reduced hormone dosage was kept constant or the hormone was omitted altogether. As might be expected, elevation of the sedimentation rate subsided more slowly than did the clinical manifestations of these withdrawal reactions. In general, clinical withdrawal symptoms lasted for only three to 10 days, but rebound elevation of the sedimentation rate did not subside entirely for periods varying from one week to three months. A withdrawal reaction involving only the sedimentation rate is illustrated in figure 1.

The effect of withdrawing pituitary adrenocorticotropic hormone in one patient (case 18) is of especial interest and worthy of further consideration. This patient is the girl aged 17 to whom reference has already been made in connection with the effect of the hormone on congestive heart failure. She had had persistent smoldering active rheumatic fever for about three and one half years prior to therapy, but during this period she did not have any fever. When after seven weeks of treatment the dose was reduced to 10 mg. per day and a little later omitted entirely, fever developed with the patient's oral temperatures reaching as high as 103.5 F. During the next 10 weeks fever persisted except for varying intervals when the patient was treated with aspirin (acetylsalicylic acid), ascorbic acid in large doses or more pituitary adrenocorticotropic hormone. All antirheumatic therapy was finally omitted a little over two weeks ago, and so far the temperature has remained normal. A careful search has been made for possible causes for the fever, unrelated to rheumatic fever, but so far none has been found; therefore it seems quite possible, in spite of the lack of other obviously rheumatic manifestations, that the febrile withdrawal reaction in this patient represents a recrudescence of rheumatic fever.

UNTOWARD REACTIONS

From the previous discussion of the effect of pituitary adrenocorticotropic hormone on congestive heart failure it is evident that in a number of instances this condition was aggravated during the early period of hormone therapy. The tendency of the drug to cause water retention may in turn be due to its sodium-retaining effect or in part to a direct effect on the kidneys of contaminating antidiuretic principles in the hormonal preparation. Whatever the cause, the effect constitutes a distinct risk for the patient with severe carditis. Fortunately in our patients aggravation of congestive failure was adequately controlled by the use of diuretics and a diet exceedingly low in sodium.

The only other serious untoward reaction which can be reasonably attributed to pituitary adrenocorticotropic hormone therapy in this series of 20 patients is a single instance of severe mental depression. This latter condition developed in a woman aged 21 (case 2) after treatment for about one month but disappeared again one month after discontinuation of hormone treatment.

One patient with severe active carditis and chronic congestive failure (case 13) was treated with the hormone in gradually reduced dosage for about three months. Toward the end of this period, while he was receiving only 4 mg. per day, there developed bilateral thrombophlebitis of the internal jugular veins and he died shortly thereafter. Although the possibility must be considered that the hormone may have played a role in the development of this fatal complication, other contributory factors to be considered are active rheumatic fever, congestive failure with venous stasis and the mercurial diuretic which was administered frequently in an attempt to combat the congestive failure.

Other relatively minor side effects from pituitary adrenocorticotropic hormone were transient headache in two cases, slight striae in two cases, acne in seven cases and development of varying degrees of roundness of the face in eight cases. The latter two manifestations usually became apparent during the second to fourth week of treatment and lessened gradually after discontinuation of therapy. In eight patients there developed no side reactions whatsoever. Significant elevation of the blood sugar level, glycosuria and hypertension were not observed in any of the 20 patients of this series.

THERAPEUTIC WORTH OF THE HORMONE

The prompt reduction in fever, the rapid disappearance of joint symptoms and the other immediate effects of pituitary adrenocorticotropic hormone therapy (indicated in table 4) which have already been discussed are extremely impressive. It must be pointed out, however, that the assessment of antirheumatic agents should not be based on immediate effects alone. If a drug is to have real value in the treatment of rheumatic fever it must do one or more of the following things: (1) shorten the course of the attack of rheumatic fever; (2) suppress active carditis, and (3) prevent or reduce residual cardiac damage.

Data relative to duration of the observed attacks of rheumatic fever in the first 19 patients of this series in whom hormone therapy has been completed are presented in table 2. The attacks were not considered to have been terminated until the effects of the withdrawal reactions, in those cases in which such reactions occurred, also subsided. Duration of active rheumatic fever is recorded in the table in two ways: (1) duration of clinical manifestations without regard to laboratory observations, and (2) total duration of rheumatic activity based on both clinical and laboratory results, especially the erythrocyte sedimentation rate.

One patient (case 19) with moderately severe chorea failed to show any improvement after ten days of therapy with large doses of pituitary adrenocorticotropic hormone. Another patient (case 13) died of a complicating jugular thrombophlebitis after about three months of therapy. A third patient (case 18) with previous persistent low grade rheumatic fever has continued to have active rheumatic fever in spite of therapy. As has already been indicated in a previous discussion, it is even possible in this case that the rheumatic process has actually increased in severity since discontinuation of the course of pituitary adrenocorticotropic hormone. A fourth patient (case 3), although finally recovered from rheumatic fever, must be considered a therapeutic failure because she did not seem to improve during the period of hormone treatment.

Of the remaining 15 patients final clinical recovery was observed in five patients within only one week of hormone therapy, in six patients within two to four weeks after the beginning of treatment and in four patients not until six to eight weeks after the first injection of the hormone. If the analysis is done on the basis of laboratory tests, particularly the erythrocyte sedimentation rate, as well as clinical manifestations, the time which elapsed between the initial dose of pituitary adrenocorticotropic hormone and apparent complete recovery was one to two weeks in two patients, four weeks in four patients, one to two months in four patients, and two to four months in four patients.

One patient (case 2), the woman aged 21 to whom reference has been previously made, was observed in her seventh attack of rheumatic fever and was treated with the hormone after she had been extremely ill for about seven weeks. Her sedimentation rate had been observed frequently to be slightly elevated prior to the onset of the last rheumatic recurrence. The patient made an excellent initial response to therapy, and all clinical manifestations completely subsided about seven weeks after she received the first dose of the hormone. However, during a 12 month follow-up since completion of treatment her sedimentation rate has continued at a slightly elevated level, a level comparable to that which had been present prior to her last recurrence of rheumatic fever.

Returning now to the question whether or not pituitary adrenocorticotropic hormone shortened the course of the rheumatic fever attacks, it is our impression from the data presented here that, in spite of obvious therapeutic failure in four instances, the duration of the rheumatic process in many of the patients was considerably less than it would have been without therapy. This impression is particularly strong when we assess the course of the hormone-treated patients in the light of our previous experience at the House of the Good Samaritan with patients whose illnesses have been of comparable severity. Nevertheless, it should be emphasized that it is strictly an impression. The well known variability of rheumatic fever even when it is uninfluenced by therapy, the variable course of the disease in the patients treated with pituitary adrenocorticotropic hormone and the relatively small number of patients so treated necessitate postponement of final judgment until there has been an opportunity to observe the effect of the hormone on a large number of patients with rheumatic fever and to compare the clinical course of these patients with that of an adequate group of controls.[10]

In regard to the second criterion of antirheumatic activity, namely, the suppression of active carditis, final judgment must also be postponed until our experience has been more extensive. Nevertheless there are indications from our data that active carditis was actually suppressed by pituitary adrenocorticotropic hormone in at least some of the patients. These indications are as follows:

1. *Rapid Disappearance of Signs of Pericarditis.*—This phenomenon was observed in six patients (see table 4).

2. *Regression and Disappearance of Significant Murmurs.*—These changes were observed in five early cases.

3. *Effect on Congestive Heart Failure.*—The fluid-retaining effect of pituitary adrenocorticotropic hormone and the consequent risk of increasing congestive failure, especially early in the course of treatment, has already been discussed. Nevertheless, the severity of congestive failure in four of the six patients with this manifestation was notably diminished after two to four weeks of hormone treatment. Since active carditis plays a primary role in the production of congestive failure in young rheumatic fever patients, it is reasonable to believe that the observed improvement in congestive manifestations reflected a reduction in the severity of carditis.

4. *Effect on Subcutaneous Nodules.*—The apparent suppression by pituitary adrenocorticotropic hormone of this proliferative rheumatic lesion in four patients suggests that the hormone may have a similar effect on the myocardial lesions which in microscopic architecture often closely resemble subcutaneous nodules.

5. *Necropsy Observations in One Patient Who Died of Jugular Thrombophlebitis.*—Microscopic examination of the myocardium and endocardium revealed areas consistent with a subacute or healing process, but Aschoff bodies were not observed and fibrinoid changes were minimal.

The third and final criterion to be considered in the assessment of pituitary adrenocorticotropic hormone is whether it reduces or prevents residual heart damage. In many respects this effect is intimately related to the effect on active carditis because it seems reasonable to believe that if the inflammatory process in the heart can be suppressed residual damage to the heart can also be prevented or at least reduced. Therefore such observations as those outlined in connection with the problem of carditis lead us to hope that the hormone may also prevent heart damage, especially if treatment can be instituted early.

Among the first 18 patients, all of whom we had the opportunity to observe for one month or longer after the discontinuation of hormone therapy, there was only one patient (case 6) in whom significant murmurs were not heard during the acute attack. In two other patients (cases 1 and 7) obviously significant murmurs heard early in the course of the illness subsequently disappeared. All three patients have continued to have apparently normal hearts during a follow-up period of 11 months. However, in view of the occasional insidious development of valvular disease several years after an original attack of rheumatic fever, a considerably longer period of follow-up study will be necessary before we can be assured that the hearts of these three patients have escaped damage. Furthermore, final assessment of pituitary adrenocorticotropic hormone therapy in regard to the prevention of residual heart damage will require observations of many additional early cases and a careful follow-up study of such cases.

In general, then, final conclusions are not yet warranted with regard to the therapeutic worth of pituitary adrenocorticotropic hormone as an antirheumatic agent. Nevertheless, there are strongly suggestive indications that in some cases the hormone may be effective in shortening the course of rheumatic fever attacks and in suppressing active carditis. There is also reason to be hopeful that such therapy when given early in an attack of rheumatic fever may prevent or decrease residual heart damage.

From our limited data we have not been able to correlate the results of treatment with the dosage of the hormone. There are suggestive indications, however, that there may be some correlation of results with the duration of the rheumatic process when pituitary adrenocorticotropic hormone therapy is begun. We have the impression that early acute attacks of the disease may be more readily controlled than attacks which have already been in progress for many months before treatment is instituted.[11]

MECHANISM OF HORMONAL INFLUENCES IN RHEUMATIC FEVER

It seems quite likely that the influence of pituitary adrenocorticotropic hormone in rheumatic fever is indirect and depends on stimulation of the adrenal cortex and a consequent increased endogenous production of 11,17-oxysteroids, but the way in which the adrenocortical steroids in turn suppress the inflammatory rheumatic process is still not understood.

---

[10] The difficulty of obtaining an adequate group of untreated controls should be recognized.

[11] McEwen and his associates[5] also gained a similar impression from their studies.

Pituitary adrenocorticotropic hormone and cortisone have a number of interesting physiological effects.[6] These include: alterations in the metabolism of electrolytes, water, carbohydrates, fats and proteins; depression of the level of circulating eosinophils in the blood, and, at least in patients with active rheumatic fever, a decided reduction in the serum concentration of gamma globulin and in the titer of antistreptolysin O.[7a] In view of the presence of a high concentration of ascorbic acid in the adrenal cortex and the reduction of ascorbic acid content when the adrenal cortex is stimulated by pituitary adrenocorticotropic hormone,[12] a recent study [13] indicating that ascorbic acid possesses some antirheumatic activity when administered by mouth in large doses is also of interest. However, it is not known whether the observations on the physiological changes induced by hormones or the observations on ascorbic acid have any real significance in relation to the problem of the therapeutic mechanism of pituitary adrenocorticotropic hormone and cortisone in rheumatic fever.

SUMMARY AND CONCLUSIONS

The clinical effect of pituitary adrenocorticotropic hormone (ACTH) has been observed in 20 patients with active rheumatic fever. In many patients the rheumatic process was severe, and most of them had active carditis.

The initial response of fever and joint involvement was especially impressive, but pericarditis, subcutaneous nodules and other rheumatic manifestations also frequently disappeared during hormone therapy.

Withdrawal reactions with clinical manifestations of rheumatic fever or with only elevation of the sedimentation rate were sometimes observed when hormone therapy was completed. In most but not all such instances these signs of rheumatic activity again subsided spontaneously over varying periods of time without any further treatment.

Of two patients with chorea, one showed striking improvement in association with pituitary adrenocorticotropic hormone therapy; the other failed to respond to a 10 day period of treatment with the hormone in large doses.

Treatment has been completed in 17 of the 18 patients with rheumatic manifestations other than chorea. Three of these cases must be considered therapeutic failures. Although the total duration of active rheumatic fever varied greatly in the remaining 14 patients, it was our impression that, on the whole, recovery took place sooner than it would have without treatment.

The apparent response of pericarditis, congestive failure and subcutaneous nodules to pituitary adrenocorticotropic hormone in a number of patients and the complete disappearance in two patients of all significant murmurs strongly suggest that in some instances active carditis may be favorably influenced by hormone treatment. Also, there are hopeful indications that if therapy is begun early in an attack of rheumatic fever cardiac damage may be lessened or prevented

The only harmful reactions definitely attributable to pituitary adrenocorticotropic hormone in this series were retention of fluids with aggravation of congestive heart failure and, in one instance, serious mental depression. It is possible that in one patient with long-standing low grade rheumatic fever the degree of rheumatic activity was greater after discontinuation than prior to the administration of the hormone. One instance of fatal jugular thrombophlebitis was encountered, but as yet there is no definite reason to attribute this complication to pituitary adrenocorticotropic hormone therapy.

The mechanism of hormonal influences in rheumatic fever is not yet understood.

Clinical and metabolic studies by us and others before and particularly since the initial observations of Hench, Kendall, Slocumb and Polley [1] have provided evidence that cortisone and pituitary adrenocorticotropic hormone (ACTH) are powerful hormonal substances. It is probable that most, if not all, tissues of the body come within the scope of their activity. When administered to man they are capable of inducing a number of physiologic and pharmacologic alterations in addition to those involved in their favorable effects on a variety of disease states. In some circumstances there may be no distinct line of demarcation between favorable therapeutic effects and other physiological effects, some of them undesirable.

In most of the clinical conditions which have been favorably influenced by administration of these hormones there is no clear evidence of hormonal deficiency. (Exceptions are conditions of frank adrenal cortical insufficiency, such as occur primarily in Addison's disease and secondarily in panhypopituitarism.) Consequently, it appears that in many of these conditions a state of hormonal excess must be created in order to achieve therapeutic benefit If this state is of sufficient degree and duration a variety of physiological effects, desirable and undesirable, may become manifest.

For the foregoing reasons a thorough understanding of the physiological potentialities of cortisone and pituitary adrenocorticotropic hormone is essential for their safe and effective therapeutic use, particularly in conditions requiring large doses or prolonged administration. In this presentation we shall consider briefly the physiological activity of these agents, as observed in human subjects, under four headings: (1) effects on

metabolism of carbohydrate, protein and fat; (2) effects on metabolism of water and electrolytes; (3) effects on structure and function of the adrenal cortices, and (4) several miscellaneous hormonal effects.¹ It is recognized that not all of the known physiological activities of these hormones are included under these headings

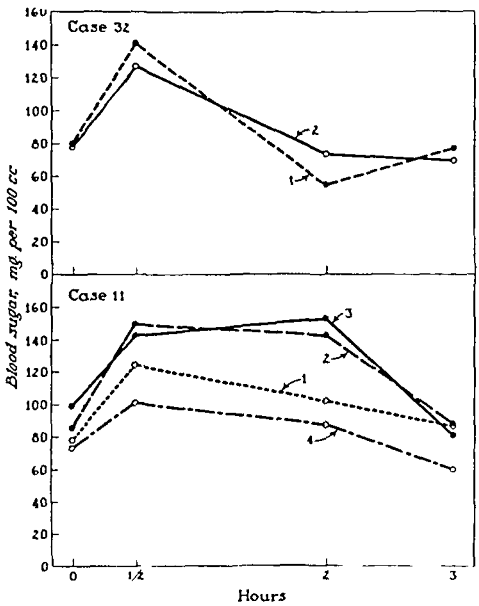

Fig. 1.—Upper (case 32). (1) Normal glucose tolerance in a woman aged 32, with disseminated lupus erythematosus, after administration of cortisone (average 112 mg. daily) for 96 days (2) Normal glucose tolerance after administration of cortisone (average 107 mg. daily) for 160 days Lower (case 11) (1) Normal glucose tolerance in a woman aged 40, with rheumatoid arthritis, before administration of cortisone (2) Impaired glucose tolerance after administration of cortisone for 7 days (average 129 mg. daily). (3) Impaired glucose tolerance after administration of cortisone, in another course, for 16 days (200 mg. daily) (4) Normal glucose tolerance 18 days after withdrawal of cortisone (reproduced from Sprague and others[4]).

EFFECTS ON METABOLISM OF CARBOHYDRATE, PROTEIN AND FAT

Carbohydrate.—That the administration of cortisone or pituitary adrenocorticotropic hormone to man might cause impairment of tolerance for carbohydrate is suggested by several earlier experimental and clinical observations: (*a*) these hormones are capable of inducing hyperglycemia and glycosuria in rats;[2] (*b*) cortisone corrects the abnormal sensitivity to insulin and the tendency to hypoglycemia exhibited by some patients with Addison's disease,[3] and (*c*) impairment of carbohydrate tolerance is a common feature of Cushing's syndrome and is apparently directly related to overproduction of cortisone-like adrenal steroids by hyperfunctioning adrenal cortices in this condition.[3b]

Inasmuch as the doses usually administered to patients are small, relative to body weight, compared to those necessary for the induction of diabetes in animals, it would be anticipated that impairment of carbohydrate tolerance in human subjects receiving these hormones would be slight or absent. In our experience this has generally proved to be the case Although slight increases in the level of the fasting blood sugar have been observed in some patients during administration of cortisone or pituitary adrenocorticotropic hormone, the values have not usually exceeded the normal range, and more than traces of sugar in the urine seldom have been observed. Among a group of patients receiving cortisone, there was no significant change in the mean value of the fasting blood sugar during or after administration of the hormone as compared to the mean value before its administration (table 1).[4]

Glucose tolerance tests have revealed a significant incidence of slight impairment of carbohydrate tolerance under the influence of cortisone. Among 12 patients, abnormal glucose tolerance curves, presumably due to cortisone, were observed in 4. It is of interest, and possibly of significance, that in 2 of these cases there was a family history of diabetes. In 2 of the 4 patients in whom impairment of glucose tolerance developed during administration of cortisone, tests which were performed after administration of the hormone had been stopped gave normal results.

In some instances no impairment of glucose tolerance was demonstrable after prolonged administration of cortisone. For example, in case 32 (fig. 1, upper) impairment could not be demonstrated after daily administration of the hormone for ninety-six days. after daily administration for 160 days, the glucose tolerance was still normal. In case 11 (fig. 1, lower) the glucose tolerance, which had been normal before administration of the hormone, was abnormal on one occasion after only seven days' administration at an average dose of 129 mg. daily and on another occasion after administration of 200 mg. daily for 16 days Eighteen days after withdrawal of cortisone the glucose tolerance was again normal.[4]

Table 1.—*Changes in Level of the Fasting Blood Sugar During and After Administration of Cortisone*

Mean Value Before Administration, Mg. per 100 Cc	During Administration		After Administration	
	Cases	Mean Difference, Mg per 100 Cc	Cases	Mean Difference Mg per 100 Cc
81.9	18	−1.5 ± 1.7*	16	−2.2 ± 2.0*

* A minus sign indicates a decrease as compared with the level before administration of cortisone The figure following the plus and minus sign is the standard error of the mean difference The mean difference is considered statistically significant if it is twice its standard error Therefore, neither of the changes tabulated above is considered statistically significant.

In contrast to this relatively benign experience with respect to impairment of carbohydrate tolerance, there have now been several cases observed elsewhere, and one at the Mayo Clinic, in which a temporary state of frank diabetes was induced by either cortisone or pituitary adrenocorticotropic hormone. In the clinic case a boy aged 4 years was found to have glycosuria and a fasting blood sugar level of 171 mg. per 100 cc after administration of 550 mg. of pituitary adrenocorticotropic hormone in six days for acute leukemia. Subsequently, glycosuria disappeared and the fasting blood sugar gradually returned to normal while the hormone was still being administered. Conn, Louis and Wheeler [5] observed impairment of glucose tolerance and fairly pronounced glycosuria in three normal adults who received 120 to 150 mg. of the agent daily for eight to 10 consecutive days. The glycosuria was apparently related in part to lowering of the renal threshold for glucose.

In a case recently studied by Pearson and Eliel,[6] in which the patient, a boy aged 17 years, received exceptionally large doses of cortisone and pituitary adrenocorticotropic hormone as treatment for acute granulocytic leukemia, pronounced glycosuria and ketonuria developed with a blood sugar determination of 505 mg. per 100 cc. and severe acidosis. The patient had not previously been known to have diabetes, nor was there a family history of diabetes. The two hormone agents were withdrawn and 400 units of insulin were employed for treatment of the condition. Death occurred from hemorrhage three days later. The blood sugar level on the day of death was 300 mg. per 100 cc., and the urine was free of sugar and ketone bodies. At necropsy no definite lesions were found in the pancreas; normal-appearing islet cells were present. In another case studied by McEwen,[7] a girl aged 10 years with acute Still's disease, who was not previously known to be diabetic, excreted up to 90 Gm. of glucose in the urine in 24 hours while receiving cortisone. There was evidence that the glycosuria was in part renal and in part diabetic in character.[8] The changes reverted to normal 22 days after administration of the hormone was stopped.

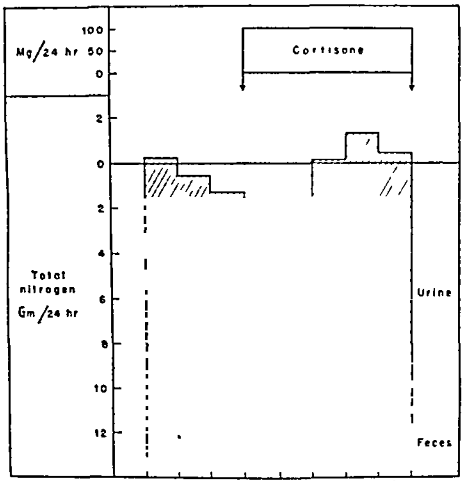

Fig 2—Slight effect of cortisone (100 mg daily) on nitrogen balance in a man aged 34, with rheumatoid arthritis and spondylitis In this figure, and in figure 3, the daily intake of nitrogen is charted from the 0 line downward and the average daily excretion (feces below, urine above) from the bottom line upward A negative balance is therefore indicated by extension of the column above the 0 line, and a positive balance by a clear area below the 0 line

Such exaggerated diabetogenic effects as those just described may indicate that the persons in question had latent diabetes prior to administration of the hormones. Indeed, temporary intensification of preexisting diabetes by cortisone has been observed by Boland and Headley [9] and by Perera and associates.[10] From a practical point of view, it is clearly wise to test the urine for sugar at intervals in both diabetic and nondiabetic persons receiving cortisone or pituitary adrenocorticotropic hormone.

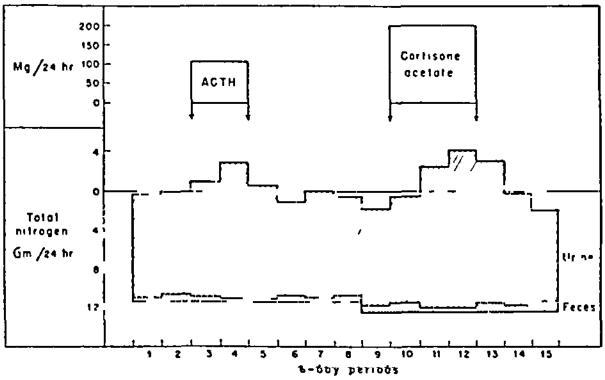

Fig 3—More pronounced effects of pituitary adrenocorticotropic hormone (ACTH) (105 mg daily) and cortisone (200 mg daily) on nitrogen balance in a woman aged 40, with rheumatoid arthritis

Protein.—Our investigations of the influence of the two agents on protein metabolism have consisted of studies of nitrogen balance and the urinary excretion of uric acid, creatine and creatinine.

Cortisone in doses of 100 mg. daily usually induced only slight increases in excretion of total nitrogen (fig. 2). With large doses of cortisone (200 mg. daily) and pituitary adrenocorticotropic hormone (105 mg daily), however, there was a rather decided loss of nitrogen from the body, indicative of an increase in the catabolism of protein under the influence of these hormones (fig. 3). Likewise, the retention of nitrogen which was observed when the effects of the administered hormones had waned is indicative of an antecedent loss of protein.

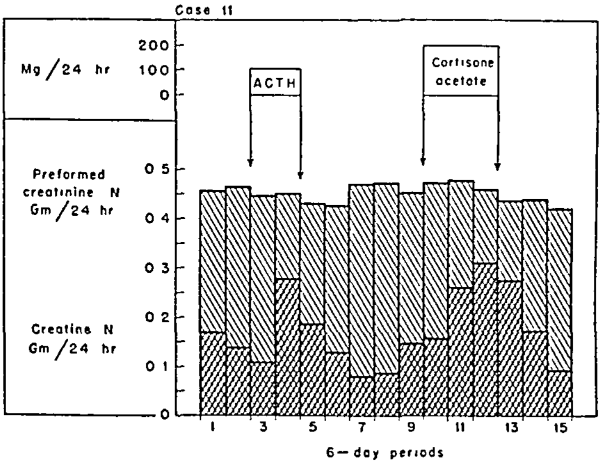

Fig 4—Effect of pituitary adrenocorticotropic hormone (ACTH) (105 mg daily) and cortisone (200 mg daily) on urinary creatine and creatinine, expressed as nitrogen, in a woman aged 40, with rheumatoid arthritis (reproduced from Sprague and others [4]).

Pronounced creatinuria was commonly observed when large doses of the hormones were administered (fig. 4). This observation may also indicate increased breakdown of body protein, for creatinuria commonly occurs in association with catabolism of muscular tissue. Likewise, an observed increase in the excretion of uric acid under the influence of the hormones, sometimes unassociated with significant change in the level of the serum uric acid, is probably consistent with the same general interpretation.

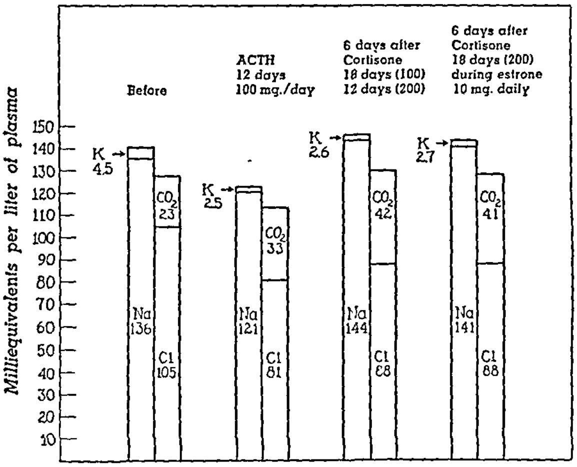

Fig. 5. — Changes in plasma sodium, potassium, chloride and carbon dioxide during and after administration of pituitary adrenocorticotropic hormone (ACTH) and cortisone to a woman aged 45, with rheumatoid arthritis.

The effects of the two agents on protein metabolism may be related to the inhibition of hair growth[11] and tumor growth[12] which has been observed in experimental animals, to the development of cutaneous striae in human subjects[4] and to the delayed healing of wounds[13] which has been observed in animal and human subjects during administration of these or related hormones.

Fat.—There is evidence that cortisone and pituitary adrenocorticotropic hormone exert an influence on metabolism of fat, but knowledge of these effects in human subjects is fragmentary. We have already referred to the occurrence of ketonuria in a subject in whom a temporary diabetic state was induced by the administration of cortisone.[6] Severe ketonuria was induced by cortisone in our subjects with coexisting Addison's disease and diabetes.[14] Transient ketonuria was observed by Perera and associates in some patients during administration of 80 mg. of cortisone daily. Thorn and his associates[15] have reported a transient increase in blood ketones during administration of cortisone in five of six patients who had Addison's disease.

Conn and others[16] have reported a decrease in the level of the serum cholesterol esters under the influence of pituitary adrenocorticotropic hormone and have suggested that esterified cholesterol is withdrawn from the blood for the synthesis of steroid hormones by the adrenal cortices when they are stimulated by this agent.

The occurrence of fatty livers in some patients with Cushing's syndrome[17] and in rats treated with the pituitary hormone[18] suggests the possibility that this phenomenon might occur in human subjects as a consequence of prolonged stimulation of the adrenal cortices with the agent. Apparently this has not yet been reported.

Abnormal distribution of fat, resembling that observed in Cushing's syndrome, may occur in patients in whom an excess of adrenal steroids is maintained for prolonged periods by administration of cortisone or pituitary adrenocorticotropic hormone. The trunk and neck appear obese, and the contour of the face becomes rounded. In most instances rounding of the facial contour has been associated with considerable gain in body weight. This has not always been the case, however, for significant rounding of the face was observed in two of our patients during administration of cortisone while the food intake was maintained at a constant level so that there was little or no change in body weight. The altered facial contour is apparently a consequence of deposition of fat in the cheeks. It has been the earliest and most obvious sign of abnormal distribution of fat which we have observed in patients receiving either of the hormones.

EFFECTS ON METABOLISM OF WATER AND ELECTROLYTES

Sodium Chloride and Water.—The characteristic effect of cortisone and allied hormones on electrolyte metabolism was formerly thought to be loss of sodium chloride and water from the body.[19] It now appears that its effects are variable. In some circumstances it may cause a retention of salt and water, sometimes of sufficient degree to produce edema. In other instances, in spite of continued administration of cortisone the retained salt and water may be excreted and edema dis-

Table 2.—*Changes in Eosinophil Count in Response to 25 Mg. of Pituitary Adrenocorticotropic Hormone Before, During and After Administration of Cortisone in a Case of Rheumatoid Arthritis and Spondylitis*

	Eosinophils per Cu. Mm.		
	8:00 A. M.	12:00 M.	% Change

appear. The factors involved in the variable effects of the hormone on electrolyte metabolism are not well understood. One possible factor is depression of endogenous production of adrenal cortical hormones under the influence of the cortisone.

In our experience the administration of pituitary adrenocorticotropic hormone in doses of 100 mg. daily has almost uniformly caused an early retention of salt and water, followed by increased excretion while the hormone was still being administered or following its withdrawal.

In some clinical circumstances the initial retention of salt and water under the influence of one or the other agent may impose hazard on the patient. This is particularly true in the presence of heart disease or hypertension.

Cortisone in a dose of 200 mg. daily and pituitary adrenocorticotropic hormone in a dose of 100 mg. daily have been observed to cause the development of hypochloremic, hypopotassemic alkalosis, similar in all respects to that observed in some cases of Cushing's syndrome (fig. 5). Thus far all our patients in whom significant alkalosis has developed have been women. In most instances the alkalosis which has resulted from administration of pituitary adrenocorticotropic hormone has differed from that due to cortisone in that there has been some lowering of the level of plasma sodium with the former but not with the latter. After withdrawal of the hormones the concentrations of the plasma electrolytes have reverted to normal, rapidly in the case of pituitary adrenocorticotropic hormone and more slowly in the case of cortisone.

Potassium.—An increased excretion of potassium, with the development of negative potassium balance, has been a characteristic response to large doses of either hormonal agent in all our cases in which balance studies were conducted. The metabolic bookkeeping indicates that the potassium which is lost from the body is derived from the intracellular as well as from the extracellular fluid. The portion of the excreted potassium which originates within the cells is another manifestation of the catabolism of cellular protein which may take place under the influence of these hormones.

EFFECTS ON STRUCTURE AND FUNCTION OF THE ADRENAL CORTICES

Pituitary Adrenocorticotropic Hormone.—The physiological effects of this hormone are contingent on stimulation of the adrenal cortices to increase their output of steroid hormones. Evidence indicates that all known functions of the adrenal cortices are augmented by this agent. Morphologically this stimulation is expressed as hypertrophy and hyperplasia of the cortical tissue. All evidences of stimulation regress rapidly when administration of the hormone is stopped.

Cortisone.—In general, the effects of cortisone on adrenal cortical structure and function are the opposite of those of pituitary adrenocorticotropic hormone. When cortisone or other adrenal hormones which have similar physiological activity are administered to rats, atrophy of the adrenal cortices eventually ensues.[20] A clinical counterpart of this process is seen in patients who have a hyperfunctioning tumor of the cortex of one adrenal gland, particularly when the hormonal activity of the tumor is such as to induce Cushing's syndrome. In such patients the contralateral gland is likely to be atrophic and functionally deficient.[21]

The foregoing observations suggest that cortisone might cause atrophy of the adrenal cortices in the human being and that adrenal cortical function might be depressed during, and for an interval following, administration of the hormone, particularly if large doses had been employed for a prolonged period. We have, in fact, observed four types of evidence suggestive of adrenal depression by cortisone: (1) postcortisone asthenia; (2) depression of urinary 17-ketosteroids during and after administration of cortisone; (3) diminished response to pituitary adrenocorticotropic hormone (test of Thorn, Forsham, Prunty and Hills [22]), and (4) atrophy of adrenal cortices observed at necropsy.

Table 3.—*Weight of Adrenal Glands After Administration of Cortisone (Necropsy Cases)*

			Cortisone		Weights of Adrenal Glands, Gm.		
Sex	Age, Yr.	Diagnosis	Total Amount, Gm.	Days Since Last Dose	Right	Left	Total
F	65	Acute leukemia	3.9	8	4.7	3.9	8.6
F	5	Acute leukemia	4.4	9	1.4	1.3	2.7

M	40	Periarteritis nodosa	2.8 0.825	12	...	...	12.5
M	48	Periarteritis nodosa	2.65 1.875 8.825	22	4.8	3.9	8.7
M	60	Rheumatoid arthritis, hepatitis	1.4 0.7	38	10.0	11.0	21.0

1. *Asthenia Following Withdrawal of Cortisone.*—Beginning a few days to a week after administration of cortisone is stopped, patients may complain of weakness and exhaustion. These symptoms may persist for a few days to several weeks but eventually abate. Although the asthenia cannot be attributed with certainty to adrenal cortical insufficiency, no other basis for it has been apparent in most of our cases. Furthermore, there have been other more tangible evidences of adrenal insufficiency, which are described later.

2. *Urinary Steroids During Administration and After Withdrawal of Cortisone.*—With the exception of cases in which the excretion of 17-ketosteroids was initially low, there was almost uniformly a prompt decrease in urinary 17-ketosteroids soon

[22] Thorn, G. W.; Forsham, P. H.; Prunty, F. T. G., and Hills, A. G.: A Test for Adrenal Cortical Insufficiency: The Response to Pituitary Adrenocorticotropic Hormone, J. A. M. A. **137:** 1005-1009 (July 17) 1948.

after administration of cortisone in a dose of 100 mg. daily was started.[4] In some cases the levels of 17-ketosteroids remained low for variable periods following prolonged administration of the hormone. These observations would seem to indicate depression by cortisone of at least some functions of the adrenal cortices.

3. *Response of the Adrenal Cortices to Pituitary Adrenocorticotropic Hormone.*—The third evidence of depression of adrenal cortical function by cortisone is a diminished response to a single 25 mg. dose of pituitary adrenocorticotropic hormone as measured by changes in the number of circulating eosinophils (test of Thorn, Forsham, Prunty and Hills[22]). Prior to administration of cortisone, the response to the other hormone was normal in all our patients. During administration of cortisone, the response was abnormal in six of eight tests. After administration of cortisone had been stopped for varying periods of time, the responses were variable, being normal in six tests and abnormal in seven tests.[4] The interval since the last administration of cortisone varied from 10 to 129 days in the six tests in which the response was normal, and from six to 33 days in the seven tests in which the response was abnormal. In all cases in which the test was performed at intervals after administration of cortisone had been stopped, the response eventually became normal. Data in one typical case are shown in table 2.

Thus, if it can be assumed that cortisone does not induce a change in the eosinophils themselves which makes them less responsive to adrenal cortical steroids, the results of these tests suggest that cortisone is capable of temporarily diminishing the responsiveness of the adrenal cortices to exogenous pituitary adrenocorticotropic hormone.

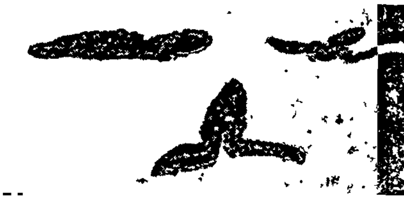

Fig. 6.—Upper: Cut surfaces of atrophic left and right adrenal glands of a girl, aged 5 years, with acute leukemia, nine days after completion of administration of 4.4 Gm. of cortisone. Lower: Cut surface of normal adrenal gland of child of same age, for comparison.

4. *Anatomic Atrophy of the Adrenal Cortices.*—Our associate, Dr. W. A. Bennett, has now had the opportunity to examine the adrenal glands at necropsy in nine cases of acute leukemia, periarteritis nodosa, disseminated lupus erythematosus and rheumatoid arthritis with hepatitis in which cortisone had been administered. The weights of the adrenal glands, together with figures for the total amount of cortisone administered and the number of days between the last dose of cortisone and death, are shown in table 3. Although there is a paucity of consistent data on normal adrenal weights in patients at various ages, and particularly in those dying of the diseases in question, the weights in some of these cases are significantly below recorded figures for supposedly normal adrenal glands.[23] For example, it appears that the atrophy was particularly pronounced in the cases of two children, ages 5 and 3 years, who died of acute leukemia nine days and one day, respectively, after receiving the last dose of cortisone. In these cases the combined adrenal weights were 2.7 and 2.9 Gm. The adrenals in the child aged 5, together with a normal adrenal from a child of the same age for comparison, are shown in figure 6. Histologically, the glands exhibited depletion of lipoid material, particularly in the zona fasciculata, which was significantly narrowed. The glomerulosa was well preserved. Dr. Bennett remarked that the glands had the gross and microscopic appearance of adrenal glands which had become atrophic as a consequence of anterior pituitary insufficiency. Indeed, suppression of the adrenocorticotropic function of the anterior pituitary is probably one of the mechanisms, if not the only one, by which cortisone may induce atrophy.

Is the apparent anatomic atrophy and depression of function of the adrenals induced by cortisone of any clinical importance? Experience to date is hardly adequate to provide an answer to this question. We know of no reason to suspect that the alterations of structure and function are not reversible after administration of cortisone is stopped. It is within the realm of possibility that adrenal cortical function in a person who had recently received cortisone might be inadequate under conditions of stress, such as trauma or fever; however, we have not yet encountered such a circumstance.

OTHER HORMONAL EFFECTS

Brief reference to some of the other hormonal effects of cortisone and pituitary adrenocorticotropic hormone will serve to illustrate further that these agents influence the metabolism and function of many, if not all, tissues of the body.

Androgenic Effects.—It came as somewhat of a surprise that cortisone should occasionally induce mild acne and hirsutism in women, effects commonly associated with steroid hormones which have androgenic activity. In our experience more pronounced androgenic effects, such as masculinization of the voice and habitus and enlargement of the clitoris, have not been observed. Those androgenic effects which have been observed have regressed when administration of the hormones has been stopped. Whether cortisone itself has weak androgenic properties or is metabolized in the body to yield androgenic compounds is not known. Pituitary adrenocorticotropic hormone has also been observed to produce androgenic effects, but there is a lack of precise knowledge of what steroid compounds produced by the adrenal cortices under the influence of this hormone are directly responsible for such effects.

Effects on Menstrual Function.—In our original group of patients who received cortisone or pituitary adrenocorticotropic hormones there were 10 women who had normal or almost normal menstrual function prior to the administration of the hormones.[4] Of the 10 women, three became amenorrheic during administration of cortisone. A fourth missed a period which was due a few days before administration of pituitary adrenocorticotropic hormone was started and did not menstruate either during administration of the agent or for a prolonged interval thereafter. Three of the four who became amenorrheic were young girls who had been menstruating three years or less, suggesting that menstrual function is more easily disturbed by these hormones in the young than in the mature woman. Details of the mechanism by which menstrual function may be affected have not been elucidated.

Psychic Effects.—A wide variety of psychic reactions, presumably hormonally induced, have now been observed by us and by others in occasional patients receiving cortisone or pituitary adrenocorticotropic hormone. These have included mild degrees of stimulation, euphoria, manic behavior, depression and frankly psychotic states. Although milder degrees of stimulation and euphoria are explainable as normal reactions to abrupt improvement in physical condition, the more severe reactions obviously cannot be so readily explained. Present evidence suggests that severe reactions are most likely to occur in persons with a background of nervous instability.

SUMMARY

Accumulated evidence indicates that cortisone and pituitary adrenocorticotropic hormone (ACTH) are powerful hormonal agents which are capable of influenc-

---

[23] Benner, M. C.: Studies on the Involution of the Fetal Cortex of the Adrenal Glands, Am. J. Path. 16:787-798 (Nov.) 1940.

ing the metabolism of many, if not all, tissues of the body. Some of these effects have favorable therapeutic implications, others are relatively unimportant, while still others may impose hazard on the patient. It is apparent that an awareness of the widespread physiological potentialities of these agents is a prerequisite for their safe and effective use in the treatment of disease.

EFFECTS OF PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) ON THE HYPERSENSITIVE STATE

JOHN EAGER HOWARD, M D.
A McGEHEE HARVEY, M D.
RICHARD A CAREY, M D.
and
WALTER L. WINKENWERDER, M D.
Baltimore

Rich and his co-workers noted that certain anatomic lesions in drug hypersensitivity and in periarteritis experimentally induced by horse serum bear a close resemblance to those of the rheumatic diseases.[1] This observation led to speculation as to the possible role of hypersensitivity in the causation of rheumatic fever, rheumatoid arthritis, lupus erythematosus and periarteritis nodosa. Therefore, when Hench and his group reported the dramatic effects of cortisone and pituitary adrenocorticotropic hormone (ACTH) in patients with these diseases it seemed possible that the clinical improvement might be due to some change in hypersensitivity induced by these agents. Accordingly, experiments were begun to test the effectiveness of pituitary adrenocorticotropic hormone in patients with diseases clearly due to hypersensitive reactions.[2] A brief review of our experience with 23 patients with asthma, 5 with serum disease type of reaction to penicillin, 2 with sympathetic ophthalmia and 2 with ophthalmic and skin sensitivity to atropine forms the basis of this report.[3] Most of the patients were given pituitary adrenocorticotropic hormone; to a few cortisone was given.

ASTHMATIC PATIENTS GIVEN PITUITARY ADRENOCORTICOTROPIC HORMONE

Nineteen patients with asthma have received courses of pituitary adrenocorticotropic hormone. Six of these were given two or more courses. Five patients have received cortisone, and four of these have later been given treatment with pituitary adrenocorticotropic hormone. The asthmatic patients all were suffering with the severe chronic form of disease, intractable to the usual therapeutic measures. All were considered to have asthma of the intrinsic type; in three it was thought to be due to both intrinsic and extrinsic factors.

Results of the first courses of pituitary adrenocorticotropic hormone may be summarized as follows: There was complete remission of all subjective and objective evidence of asthma in 15 of the 19 patients. They usually began to notice some improvement within a few hours of the first dose; complete remission, however, did not occur in one patient until the eleventh day of therapy. Symptomatic therapy was reduced to an absolute minimum after hormone therapy was begun, the patients being allowed but one type of agent such as isopropylarterenol (isuprel®) hydrochloride spray or aminophylline suppository except in exceedingly severe attacks. Reduction in requirement of such adjuvant therapy served as an excellent guide to the clinical course.

The dosage schedule in those patients who achieved a complete remission varied: usually 100 mg. of pituitary adrenocorticotropic hormone (Armour standard)[4] was given daily for the first two days, the amount being gradually reduced to 20 mg, the courses lasting from six to 21 days. The daily dose was always divided into four equal parts, given intramuscularly at six hour intervals. The total amount given to this group of patients ranged from 193 to 1,248 mg.

The duration of complete remission from asthmatic symptoms and signs has varied from three to more than 263 days. There is a rough correlation between the dosage and the duration of remission. The two patients who had the briefest periods of complete comfort received much the smallest and shortest courses of the hormone; however, the patient who received the largest dose manifested beginning asthmatic recurrence two weeks after completion of the course.

Four patients failed to achieve complete remission of their asthma. One was in the sixth and seventh months of pregnancy: although she experienced complete subjective relief on the fifth day of pituitary adrenocorticotropic hormone therapy, the auscultatory rhonchi never entirely disappeared. Two days after therapy was stopped, coincident with an upper respiratory infection, the asthma increased in severity and epinephrine was required. The second patient, who had had asthma more than 40 years, achieved approximately 60 per cent relief but still had to be given spray or injections on humid days. The other two patients who failed to have complete remission from asthma were later discovered to have received only half the scheduled dose of the hormone, owing to an error in assay. To this date none of the patients who have relapsed have had asthma of the same severity as before taking pituitary adrenocorticotropic hormone, as judged by either themselves or their physicians.

ASTHMATIC PATIENTS GIVEN MORE THAN ONE COURSE

Six patients in the first series have been given second or third courses of pituitary adrenocorticotropic hormone. All of these had responded to initial courses with complete remissions. Response to the drug was just as prompt in each instance as with its initial use.

ASTHMATIC PATIENTS TREATED WITH CORTISONE

Cortisone has been given to five patients with asthma. With a single exception, their asthma was similar in type and severity to that of the group who received pituitary adrenocorticotropic hormone. In the first four patients the dose of cortisone was 200 mg. on the

first day and 100 mg. daily thereafter for seven days. The daily dose was divided into four equal parts and administered intramuscularly at intervals of six hours. A second course with double dosage was given to one patient 45 days after the first course, at a time when the asthma was approximately of equal severity. Only one patient in this group achieved complete subjective and objective remission; his asthma was mild as compared with that of other members of this series. The medicament was given to him primarily to note its effect on a large accumulation of nasal polyps. The other patients experienced only partial relief manifested by reduction in the requirement of antiasthmatic drugs, estimated variously as 25 to 50 per cent improvement. No better clinical improvement than after the initial course was noted during the second course with a double dose of cortisone by the one patient in whom this was tried.

A comparison of the results in this small group of patients with those in the group treated with pituitary adrenocorticotropic hormone would indicate that, at these dosage levels, cortisone compares unfavorably with the pituitary hormone in alleviating the symptoms and signs of chronic bronchial asthma. This conclusion is further substantiated by the results of retreating three of these patients with pituitary adrenocorticotropic hormone 50, 75 and 60 days after the unsuccessful courses of cortisone had been completed. In each of these three instances complete remissions of the asthma were induced. Furthermore, these same patients experienced partial symptomatic relief with this agent considerably earlier than they had with cortisone.

DRUG HYPERSENSITIVITY

Four patients with severe serum disease type of reaction to penicillin were given pituitary adrenocorticotropic hormone, initial doses being 100, 85 and 50 mg. Administration was continued four, five, six and nine days. Total dosage ranged from 145 to 635 mg. Beneficial response occurred in 6 to twelve hours; all subjective and objective signs, including fever, skin and joint manifestations, had disappeared within 72 hours.

A single patient with the same type of reaction to penicillin was given cortisone, 400 mg. the first day and 200 mg. for four succeeding days. No clinical benefit was noted until the third day, at which time urticaria improved slightly, joints were a little less swollen and painful, and fever fell. On the fourth day the temperature fell to normal; there was further minimal improvement in joints and skin. The patient insisted on leaving the hospital after the fifth day, and symptoms subsided gradually, not being entirely absent until five weeks after discharge.

Ophthalmic and skin sensitivity to atropine was reduced in two patients by pituitary adrenocorticotropic hormone. In one patient ocular sensitivity to atropine developed during treatment of sympathetic ophthalmia. During administration of ACTH instillation of atropine was reinstituted without reaction until the hormone dose was lowered to 20 mg. per day, at which time the typical lesions reappeared. At a later time atropine was readministered when the dose of the hormone was 40 mg. per day, and no reaction appeared.

The second patient had manifested dermatologic and ocular sensitivity to atropine and scopolamine during treatment for recurrent uveitis. For four months there had been violent dermatitis of the periorbital and facial skin together with conjunctival reaction. A patch test to atropine produced a severe response similar to the facial lesions. Within 48 hours after pituitary adrenocorticotropic hormone was given, the pericorneal congestion had faded, the erythema and edema of the skin subsided and the intraocular tension became stabilized. On the eighth day of hormone administration, while the patient was receiving 120 mg. per day, the atropine patch test was repeated and only a faint erythema resulted.

Two patients with sympathetic ophthalmia, a disease thought to result from hypersensitivity to uveal pigment,[5] responded with rapid improvement to pituitary adrenocorticotropic hormone. Evidence of inflammation and exudation began to recede within 48 hours, though edema and bogginess of the iris—the so-called organic features—did not seem to be affected.

COROLLARY STUDIES

Certain corollary studies on the patients with hypersensitive reactions while receiving pituitary adrenocorticotropic hormone gave the following results:

Eosinophils.—In the asthmatic patients who received pituitary adrenocorticotropic hormone, the maximum fall in blood eosinophils occurred from the second to the seventh day of drug administration. There was a reasonable correlation between the extent of eosinophil reduction and the degree of clinical improvement. However, toward the end of the course, usually when the dose became lower than 30 mg. per day, the eosinophil count rose although the asthma might still be improving or might remain completely alleviated.

All the patients with hypersensitivity to penicillin had eosinophil counts before medication which were too low for accurate evaluation of the effect of the hormone. Its effect on the circulating eosinophils of the patients with sympathetic ophthalmia and atropine sensitivity was similar to that in asthmatics.

Skin Reactions.—Six of the asthmatic patients were found, before receiving pituitary adrenocorticotropic hormone, to be skin sensitive to inhalants, and one patient to several foods. In five of these patients the immediate skin reactions were significantly reduced while they were receiving the hormone. Immediate skin reactions to bacterial antigens were significantly reduced in 10 of the 15 patients tested during administration of the drug. Delayed 24-hour bacterial reactions were reduced in 11 of the 15.

Of the six patients in whom immediate reactions to pollens and dust were obtained prior to hormone therapy, the serum reagin titer was measured in three instances by passive transfer, using the serum dilution method. The titer was not significantly altered during administration of the hormone, although the immediate skin reactions in two of these three patients were definitely reduced.

Nasopharyngoscopic Observations.—Striking changes were observed by Dr. J. E. Bordley in the nose and nasopharynx of the asthmatic patients during administration of pituitary adrenocorticotropic hormone. The edematous membranes shrank and became normal in color; discharge was reduced, and the lymphoid crypts became more prominent without visible change in the amount of lymphoid tissue present. Nasal polyps shrank, disappearing entirely in some instances. Antral clouding in roentgenograms was reduced and in some cases disappeared altogether.[2]

Antibody Formation.—Dr. George S. Mirick has made studies on the production of antibodies which may be summarized as follows: Antibodies to administered specific Pneumococcus polysaccharide were formed to approximately the same titer and at the same rate in two groups, 16 controls and 15 patients receiving pituitary adrenocorticotropic hormone or cortisone. This was true of both agglutinins and mouse-protective antibodies against Pneumococcus type 2. The latter observation seems of great practical importance and indicates that the two hormones in these doses do not lower the capacity to produce antibodies.

Response to the Francis test,[6] manifested by local erythema and wheal formation from the polysaccharide injected intracutaneously at a time when circulating antibodies are elevated, was altered by administration of pituitary adrenocorticotropic hormone. In all controls at two to three weeks, and in six patients tested one to two months after the drug therapy was stopped, the test was positive. Between two or three weeks after vaccination with the polysaccharide, of six patients tested while being treated with the hormone three showed no response at all; the other three manifested only feeble reactions. At the same time all six had good titers of circulating antibodies.

Dr. Bacon F. Chow's studies showed that nonspecific complement rose significantly in all patients studied while being given pituitary adrenocorticotropic hormone. Precipitins to the agent have not developed in any patient.

Metabolic Effects.—In none of the group of patients here reported did there develop striae or glycosuria, and none of the women manifested amenorrhea or hirsutism. One third of the patients became edematous. Significant weight gain occurred in slightly more than one half, varying from 3 to 36 pounds (1.3 to 16.3 Kg.), maximum gain being reached anywhere from the fourth to the seventeenth day of drug administration. There appeared to be no difference between pituitary adrenocorticotropic hormone and cortisone in their propensity to cause sodium and water retention. Significant rises in blood pressure occurred in 10 per cent of the patients. Fasting blood sugar rose more than 20 mg. in one third of the group, maximum rise occurring from the second to the seventh day of pituitary adrenocorticotropic hormone therapy. Acne appeared in four of the group and was severe in one, but it regressed rapidly in all after withdrawal of the drug. Only one patient manifested a fall in serum potassium below 3 milliequivalents per liter; one half of the patients showed rises in serum carbon dioxide of more than 3 milliequivalents per liter, but in none was the rise more than 9 milliequivalents. The hematocrit fell in every instance, the average fall being 7 mm. (Wintrobe); the greatest fall was 10 mm. The degree of fall in hematocrit bore no apparent correlation with the amount of weight gained.

COMMENT

It seems clear that administration of cortisone and adrenal stimulation by pituitary adrenocorticotropic hormone exert beneficial action on the clinical manifestations of bronchial asthma and certain other types of cellular hypersensitivity which are thought to be due to antigen-antibody combination. The site of operation and mechanism of this beneficial action are as yet unknown. The property of "resistance" conferred by either of the hormones appears to be quantitative, lasting for variable periods of time and capable of being "broken through" if the challenge is sufficiently great.

From the evidence thus far obtained, pituitary adrenocorticotropic hormone and cortisone may be profitably used as adjuvants in the treatment of certain allergic conditions, provided neither is used in patients to whom the other physiologic effects of these agents might prove deleterious. Benefit has been obtained in patients with severe bronchial asthma, with serum disease type of reactions to penicillin, atropine sensitivity and sympathetic ophthalmia. A patient with bronchiectasis had severe asthma as a complication, and studies to localize the site and extent of the bronchiectasis could not be performed during treatment with the usual antiasthmatic drugs. After administration of pituitary adrenocorticotropic hormone had resulted in freedom from the asthma, bronchoscopy and pulmonary visualization by iodized oil (lipiodol®) were readily performed.

SUMMARY

Pituitary adrenocorticotropic hormone (ACTH) and cortisone have been demonstrated to provide clinical improvement in certain hypersensitive states due to antigen-antibody combination. The mechanism of this beneficial action is unknown. This report summarizes the clinical observations on 23 patients with chronic intractable asthma, five with serum disease type of reaction to penicillin, two with sympathetic ophthalmia and two with atropine sensitivity.

USE OF PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) AND CORTISONE IN LYMPHOMAS AND LEUKEMIAS

O. H. PEARSON, M.D.
and
L. P. ELIEL, M.D.

The availability of a purified pituitary adrenocorticotropic hormone (ACTH)[1] and of the synthetically prepared adrenal cortical steroid, cortisone[2] (17-hydroxy-11-dehydrocorticosterone) provided means of inducing increased adrenal cortical function in man, in the first instance by stimulating the adrenal cortex to increased activity and in the second by administering a physiologically active, adrenal cortical steroid. Pituitary adrenocorticotropic hormone or cortisone acetate has been administered to 70 patients with various types of neoplastic disease during the past two years at Memorial Hospital. Among this group of patients all the clinical manifestations and metabolic alterations associated with Cushing's syndrome have been observed to develop, which is in agreement with the observations of Sprague and his colleagues.[3]

The clinical and metabolic manifestations of spontaneously occurring Cushing's syndrome have been reviewed by Albright[4] and Kepler and Locke.[5] The production of Cushing's syndrome in man by pituitary adrenocorticotropic hormone or cortisone acetate substantiates the concept of previous investigators that this syndrome is due to an overproduction of adrenal steroids with physiological properties similar to those of 17-hydroxy-11-dehydrocorticosterone. Albright has emphasized that one of the striking features of Cushing's syndrome is decided atrophy of tissues, namely, muscle, skin, bone, lymph nodes and thymus. Although the mechanisms by which the adrenal hormones exert their physiological effects are not known, Albright has

postulated that tissue atrophy results from inhibition of tissue synthesis rather than stimulation of tissue breakdown. Metabolic studies on patients receiving pituitary adrenocorticotropic hormone or cortisone acetate have demonstrated that body protoplasm is destroyed.

Animal studies have shown that either hormone inhibits growth in young animals [6] and produces atrophy of lymphoid tissues.[7] Heilman and Kendall [8] have observed that a transplantable lymphoid tumor in mice could be caused to regress by administration of cortisone. Murphy and Sturm [9] have demonstrated that decreased susceptibility to transplantable leukemia can be produced by administering pituitary adrenocorticotropic or adrenal cortical hormones. Law and Speirs [10] were able to produce remissions in spontaneous leukemia of mice with adrenal cortical extracts.

Experimental studies were therefore performed to determine whether increased adrenal cortical function would affect the rate of growth of tumors in man. Preliminary reports of these observations have been published.[11] In this paper, the clinical observations in 70 patients with various types of tumors will be presented.

CLINICAL OBSERVATIONS

Chronic Lymphatic Leukemia.—Eight patients with chronic lymphatic leukemia have received pituitary adrenocorticotropic hormone or cortisone acetate in a dosage of 100 to 200 mg. per day for periods of 18 days to three months. All these patients have shown appreciable shrinkage of enlarged lymph nodes, livers and spleens during hormone administration. In two patients regrowth of tumor masses occurred within two weeks after discontinuation of treatment. In three patients regrowth of lymphoid masses occurred slowly after six weeks to three months. Three patients died shortly after hormone administration was stopped, two with hemorrhagic manifestations and one with intercurrent infection. Four patients have shown responses to two courses of hormone administration. Two patients have had equally effective responses to three courses of treatment over a period of one year of observation. This indicates that refractoriness to administration of these hormones does not develop rapidly.

Some improvement in the hematological picture has been observed in this group of patients. In five patients a rise in reticulocyte count was followed by better maintenance of hemoglobin levels or a spontaneous rise in hemoglobin. In one patient the reticulocyte count rose to 9 per cent and the hemoglobin increased from 7 to 15 Gm. per 100 cc. Seven patients had slight, transient rises in platelet count. In all patients there was a rise in the peripheral white blood cell count during the first two weeks of treatment, in some instances to two or three times the initial level. Thereafter the leukocytes fell to below the pretreatment level in all patients. The differential white blood cell count, which was approximately 98 per cent mature lymphocytes in all patients, did not show improvement. Bone marrow aspirations, which also showed almost complete infiltration with mature lymphocytes, did not show improvement after treatment.

Subjective improvement was noted during the first two weeks of treatment in all patients. This was characterized by a sense of well-being, an improvement in appetite and an improved capacity for mental and physical work. In addition to the three deaths already described, a fourth patient died during a second course of hormone administration as a result of massive hemoptysis from a small pulmonary abscess. Of the four remaining patients, three have been able to resume their usual occupation (laborer, commercial artist and engineer). The fourth patient, although unable to work, is improved and ambulatory. All but one of these patients had previously received roentgen therapy or radioactive phosphorus. Two patients were considered to be refractory to radiation therapy. In several other patients radiation therapy did not seem to be indicated because of hemorrhagic manifestations and low platelet counts.

The therapeutic value of pituitary adrenocorticotropic hormone or cortisone acetate in this disease cannot be adequately evaluated at the present time. Complete remission of the disease does not appear to be obtainable with these hormones. The objective and subjective improvement obtained in this small group of patients suggest that these hormones are useful in the palliation of this disease. Long term observation will be required to determine whether these agents can prolong life in patients with chronic lymphatic leukemia.

Lymphosarcoma.—Six patients with lymphosarcoma have received pituitary adrenocorticotropic hormone or cortisone acetate for periods of nine to 52 days. All these patients showed definite shrinkage of lymphoid tumor masses. Four patients were in a terminal stage of their disease when treatment was started. These patients died during treatment despite transient improvement and objective shrinkage of tumor masses.

One previously untreated patient with disease apparently localized to one side of the neck showed almost complete regression of tumor masses during administration of 100 mg. of pituitary adrenocorticotropic hormone daily for 18 days. No perceptible regrowth of lymph nodes was detected during a three month period after therapy was stopped. Biopsy of two small lymph nodes which remained during this period revealed no significant pathological alteration. During the fourth month after hormone administration, gradual enlargement of lymph nodes was noted and biopsy again revealed changes consistent with lymphosarcoma. Roentgen therapy was given with complete disappearance of the adenopatny.

One patient with severe, generalized adenopathy and splenomegaly showed rapid shrinkage of lymph nodes and spleen during administration of 100 mg. of pituitary adrenocorticotropic hormone daily for 18 days. Regression of lymph nodes and spleen persisted for three months after therapy was stopped. During the fourth month slow regrowth of lymph nodes occurred, and a second course of the hormone was equally effective in reducing the size of tumor masses. After a four month interval, during which regression persisted, regrowth of lymph nodes and spleen occurred. In addition, massive right hydrothorax developed, presumably due to enlarged mediastinal lymph nodes. The fluid was aspirated from the chest, and a third course of pituitary adrenocorticotropic hormone was again as effective in shrinking the enlarged lymph nodes and spleen. Regression has persisted during a two month interval since the last course of the hormone, and there has been no reaccumulation of pleural fluid. Evidence of refractoriness to hormone administration has not been manifested in this patient during three courses of treatment over a period of one year. The patient has remained in good health throughout this period.

Evaluation of the therapeutic usefulness of pituitary adrenocorticotropic hormone and cortisone acetate in patients with lymphosarcoma will require further observations.

Acute Leukemia.—The striking shrinkage of lymphoid masses in patients with chronic lymphatic leukemia and lymphosarcoma induced by pituitary adrenocorticotropic hormone or cortisone acetate suggested the trial of these hormones in patients with acute leukemia. It has been found that temporary remissions can be induced with considerable regularity in both children and adults with acute granulocytic or acute lymphocytic leukemia. Monocytic leukemia appears to be unaffected by these hormones. Thirty patients (10 adults and 20 children) with acute leukemia have received one of these agents. Of this group, 13 (nine children and four adults) have shown a good clinical and hematological remission, nine have shown objective clinical or hematological improvement, or both, and eight have shown no response.

Symptomatic improvement usually occurred within the first few days of treatment as evidenced by development of a sense of well-being, improvement in appetite, cessation of bleeding manifestations and a subsidence of fever. Shrinkage in the size of enlarged lymph nodes, spleens and livers occurred within a few days after the start of treatment. Hematological improvement was first manifested by a rapid fall in the number of circulating white blood cells (when initially elevated), an increase in the percentage of mature, circulating leukocytes, a rise in reticulocytes and an increase in platelet count. After two to four weeks of treatment the peripheral blood was frequently normal. Bone marrow improvement was first manifested by the appearance of erythropoietic activity. Within two to three weeks of treatment mature myeloid cells increased in number. In some cases the bone marrow appeared normal during remission, but careful study usually revealed the presence of a few abnormal cells.

Remissions induced by pituitary adrenocorticotropic hormone or cortisone acetate are of short duration, varying from three weeks to two months. Refractoriness to hormone therapy develops rapidly. Although five children have responded to second courses of treatment, in all but one the hormones had to be given for longer periods and in larger dosage before a remission was obtained. Several patients who obtained remissions with a first course of treatment failed to show any response to a second period of hormone administration. Several patients who showed an initial response to treatment, but who failed to obtain a satisfactory hematological remission, relapsed and died while hormone therapy was continued.

Nine patients with acute leukemia, who had become resistant to therapy with folic acid antagonists,[12] have responded to pituitary adrenocorticotropic hormone or cortisone acetate. Similarly, three patients who had become refractory to administration of one of these agents have responded to folic acid antagonists.[12] These observations suggest that the hormones exert their beneficial effects in patients with acute leukemia by a different mechanism than that involved with folic acid antagonists.

Twenty-one patients received pituitary adrenocorticotropic hormone initially and nine were given cortisone acetate. Responses appeared to be equally good with either agent, although usually the response occurred sooner with the former than with the latter. Pituitary adrenocorticotropic hormone was administered in a daily dosage of 50 to 100 mg. to children and 100 to 200 mg. to adults in four divided doses at six hour intervals. Cortisone acetate was given in 100 to 200 mg. amounts daily to children and in 200 to 400 mg. amounts daily to adults, usually in four divided doses. Both hormones were given intramuscularly. It may be concluded from these observations that pituitary adrenocorticotropic hormone and cortisone acetate are useful in the temporary palliation of patients with acute granulocytic or lymphocytic leukemia.

Hodgkin's Disease.—Six patients with Hodgkin's disease have received pituitary adrenocorticotropic hormone or cortisone acetate. During hormone administration four of the six patients showed slight shrinkage of enlarged lymph nodes and spleens. In two patients subsidence of fever and decreased itching of the skin were also noted. One patient obtained temporary relief of mechanical obstruction to respiration. Three patients with far advanced disease died during hormone administration. In two patients with moderately advanced disease prompt recurrence of symptoms and tumor masses followed cessation of hormone administration. One previously untreated patient manifested depression and delusions after six weeks of pituitary adrenocorticotropic administration and committed suicide shortly after the hormone was stopped. These limited observations indicate that either of the two agents may produce slight, temporary improvement in patients with Hodgkin's disease, but lasting beneficial effects have not been obtained.

Plasma Cell Myeloma.—We previously reported [11b] that pituitary adrenocorticotropic hormone failed to produce any significant improvement in one patient with plasma cell myeloma. Postmortem examination subsequent to our report failed to confirm the diagnosis of plasma cell myeloma in this patient: instead, a diagnosis of anaplastic carcinoma was made. Another patient in whom the diagnosis of plasma cell myeloma appeared more nearly certain has shown symptomatic and objective improvement during pituitary adrenocorticotropic hormone and cortisone acetate administration. In this patient administration of the former agent resulted in rapid disappearance of severe pain in the extremities and back, a decided reduction of serum myeloma protein, a rise in reticulocyte count and hemoglobin level and improvement in renal function. The bone marrow, however, has remained infiltrated with plasma cells. When treatment was stopped, there was a recurrence of symptoms within 24 hours. Readministration of the hormone again resulted in striking clinical improvement. Exacerbation occurred a second time on stopping the drug. Improvement was obtained a third time with administration of cortisone acetate, and at the present time the patient feels fairly well on a maintenance dose of 50 mg. cortisone acetate daily.

---

[12] Studies in these patients were done in collaboration w Joseph H. Burchenal and will be reported in detail elsewhere.

Neoplastic Diseases in Which the Hormones Have Not Had Demonstrable Beneficial Effects.—Four patients with chronic myelogenous leukemia have received pituitary adrenocorticotropic hormone. Some shrinkage in the size of enlarged lymph nodes and spleens was noted in all four patients. No evidence of improvement in the hematological picture, however, was observed in any of these patients.

Four patients with acute monocytic or acute myelomonocytic leukemia have shown no beneficial effects from receiving either hormone. Seven patients with carcinoma, two of the breast, two of the lung and one each of the prostate, pancreas and adrenal, have not shown demonstrable shrinkage of tumors during hormone administration. Two patients with Ewing's tumor and one each with osteogenic sarcoma, rhabdomyosarcoma, synovial sarcoma, neuroblastoma and malignant melanoma have failed to show any significant change during administration of pituitary adenocorticotropic hormone or cortisone acetate.

COMMENT

Spontaneously occurring Cushing's syndrome has a fatal outcome if untreated. Within our group of 70 patients all the clinical and metabolic manifestations of Cushing's syndrome have been observed to develop as a result of administration of pituitary adrenocorticotropic hormone or cortisone acetate. The use of these hormones is therefore limited by the physiological effects produced, which may in themselves prove fatal. All, or nearly all, of the physiological effects of the agents are reversible when hormone administration is stopped. Certain physiological effects require that administration of the hormone be discontinued; other effects can be controlled without stopping hormone therapy.

Physiological Effects Which Can Be Controlled Without Stopping Hormone Administration.—1. Edema: In patients on an unrestricted diet pituitary adrenocorticotropic hormone and cortisone acetate usually produce decided retention of fluids with edema formation. Occasionally spontaneous diuresis occurs while hormone administration continues. Usually fluid retention continues until the hormone therapy is stopped, when diuresis occurs promptly. Fluid retention is probably caused by a physiological effect on the kidney producing sodium and chloride retention. Pronounced fluid retention can be prevented by restriction of sodium chloride intake (low salt diet).

2. Alkalosis, Hypochloremia and Hypopotassemia: These electrolyte changes occur frequently during administration of pituitary adrenocorticotropic hormone or cortisone acetate apparently as the result of an intracellular potassium deficit. Symptoms and signs of potassium deficit may occur: i. e., apathy, lethargy, muscular weakness or paralysis, abdominal distention and cardiac irregularities. The signs and symptoms of potassium deficit can be alleviated and the serum electrolyte changes corrected by administration of potassium chloride without stopping the hormone.

3. Glycosuria and Hyperglycemia: Diabetes occurs in a small percentage of patients receiving either of the agents. Glycosuria and hyperglycemia are usually moderate in degree and do not require treatment with insulin. The diabetes disappears when the hormone is stopped. In one patient severe diabetic acidosis developed during administration of pituitary adrenocorticotropic hormone. Treatment was stopped, and only moderate amounts of insulin were required to control the diabetic crisis.

4. Atrophy of Tissues: Metabolic balance studies of the effects of pituitary adrenocorticotropic hormone or cortisone acetate in patients with lymphoid tumors have shown that not only lymphoid tumor tissue is destroyed but normal tissues as well. Prolonged administration of either hormone in sufficient quantity may produce severe wasting of muscle and presumably of other normal tissues. Weakness and debility may be associated with this loss of muscle mass aside from the electrolyte changes described above.

A metabolic balance study in one patient with chronic lymphatic leukemia during administration of both cortisone acetate and testosterone has demonstrated that decided shrinkage of lymphoid tumor masses occurred while the patient remained in nitrogen balance. This observation indicates that involution of lymphoid tumor tissue occurred while normal tissue was being built up. Albright[4] has demonstrated beneficial effects of testosterone therapy in patients with Cushing's syndrome. It would thus appear that atrophy of certain normal tissues induced by cortisone acetate administration may be prevented by simultaneous administration of testosterone.

Physiological Effects Requiring Cessation of Hormone Administration.—1. Hypertension: Significant increases in blood pressure during administration of pituitary adrenocorticotropic hormone and cortisone acetate have been observed only in children. Severe hypertension may develop rapidly in children without obvious relationship to duration of therapy, electrolyte changes or the clinical manifestations of Cushing's syndrome. Two children suddenly manifested hypertensive encephalopathy, one during treatment with the former agent and the other during treatment with the latter. There was rapid onset of coma, convulsions, transient hemiparesis, blurring of the optic disks and elevation of blood pressure to levels of 200/140 mm. of mercury. Both patients recovered without residual signs within a few days of stopping the hormones. Significant elevation of blood pressure during hormone administration requires careful observation or immediate cessation of therapy.

2. Mental Disturbances: A sense of well-being even in the presence of debilitating disease is a frequent early effect of treatment with pituitary adrenocorticotropic hormone or cortisone acetate. Sleeplessness is frequently noted during administration of these hormones. After several weeks of hormone administration a state of depression sometimes develops. Two of our patients have committed suicide during such a state of

depression. Delusions have occurred in a few patients after several weeks of hormone administration, e. g., a sense of a peculiar body odor, a sense of shrinking of the extremities to "matchstick" size, a sense of rising into space. Depression, delusions or psychotic manifestations probably demand immediate cessation of therapy.

3. Pyogenic Infections: Lowered resistance to skin infections has been previously noted in patients with Cushing's syndrome. Prolonged administration of pituitary adrenocorticotropic hormone or cortisone acetate may impair the localization and resolution of pyogenic infections. Administration of either of the hormones should not be continued in the presence of infections which fail to respond rapidly to specific therapy.

SUMMARY

Experimental studies of the effects of pituitary adrenocorticotropic hormone (ACTH) and cortisone acetate in 70 patients with various types of neoplastic disease are reported. Administration of these hormones has produced all the clinical and metabolic manifestations of Cushing's syndrome among various members of this group of patients.

Striking temporary shrinkage of enlarged lymph nodes, spleens and livers has been produced as a result of treatment with either agent in patients with chronic lymphatic leukemia, lymphosarcoma, acute lymphatic leukemia and acute granulocytic leukemia. Slight shrinkage of enlarged lymph nodes and spleens in patients with Hodgkin's disease has been observed during hormone administration.

Temporary remissions in patients with acute lymphocytic leukemia and acute granulocytic leukemia have been induced by pituitary adrenocorticotropic hormone and cortisone acetate. Temporary clinical improvement in one patient with plasma cell myeloma has been observed with the use of the two agents.

No significant improvement from hormone administration was seen in patients with acute monocytic or myelomonocytic leukemia, chronic myelogenous leukemia, malignant melanoma, neuroblastoma and several types of carcinoma and sarcoma. These agents are useful in the temporary palliation of patients with acute lymphocytic and acute granulocytic leukemia. Their possible therapeutic usefulness in chronic lymphatic leukemia, lymphosarcoma and multiple myeloma require further evaluation.

The control of the physiologic effects of pituitary adrenocorticotropic hormone and cortisone acetate in man are discussed.

Infinity.—As new stars and galaxies, untold billions of light years distant, are discovered and as still larger and more powerful telescopes are built, there is one mystery that may never be solved by man—the mystery of infinity. . . . It was not so long ago that science taught the indivisibility of the atom. Then we learned that the atom was only Nature's building brick that could be further divided into its components. And then we were told that there are protons and positrons, electrons and neutrons—and no serious-minded scientist would wager that we have reached the end of physical or even theoretical divisibility. For that matter, many begin to doubt that there is such an end. Thus, infinity may work both ways, and no matter how powerful our artificial eyes—the telescope and the microscope—might become, they may never cover more than a limited portion of a band that has no limits and infinity on either side.—*Technical Data Digest,* November 1950, page 4.

EFFECTS OF CORTISONE IN CERTAIN NEUROMUSCULAR DISORDERS

G. M. SHY, M.D.

and
D. McEACHERN, M.D.
Montreal

The effects of cortisone have been studied in 12 patients with muscular or neuromuscular disorders. The therapeutic results in some instances were dramatic, while in others they may throw some light on the mechanism of the conditions involved.

The studies were based on four patients with proximal girdle myopathy which appeared after the menopausal or climacteric period: two with dystrophia myotonica; one with myasthenia gravis; two with disseminated lupus erythematosus with severe muscular involvement; one with juvenile muscular dystrophy with severe contractures, and, finally, two with motor neuron disease manifested by bulbar palsy and amyotrophic lateral sclerosis.

INVESTIGATION

Muscle biopsy was carried out on all patients in order to confirm the clinical diagnosis as closely as possible. Eosinophil counts, basal metabolic rates, glucose tolerance curves and serum sodium, potassium, creatinine and uric acid levels were determined at three to five day intervals. Electromyograms on each patient were obtained before and during administration of the drug and more frequently on the two patients with dystrophia myotonica. All patients were kept on a meat-free diet, and daily 24-hour urine creatine and creatinine determinations were made.[1] Intake and output of fluids were recorded daily. Blood pressures were recorded twice daily. For each patient, an initial electroencephalogram was obtained and one also at the height of medication. Weights were plotted daily. Tests of muscle power were carried out, according to the individual patient's specific weakness, at almost daily intervals. For each patient a cholesterol control period was instituted after cessation of hormone therapy.

GENERAL RESULTS

In all but one case there was a prompt fall in the circulating eosinophils within four to six days after commencement of therapy. The one exception was a case of progressive muscular atrophy in a patient who maintained a persistent unexplained eosinophilia. Glucose curves rose to near diabetic levels in all cases. Our findings, unlike those of Milhorat[2] with pituitary adrenocorticotropic hormone (ACTH), indicated that the creatine: creatinine ratio remained almost constant, a source of disappointment to us. This may have been because levels of cortisone compatible with 150 mg. of pituitary adrenocorticotropic hormone were not used.

In no cases were electroencephalographic abnormalities detected during or after cessation of administration. This is of interest in view of the high percentage of electroencephalographic changes observed by Hoefer and Glaser[3] in their studies with pituitary adreno-

corticotropic hormone. It should be remembered in this regard that these authors were dealing with different types of cases and that they were stimulating the production of many adrenal steroids in addition to cortisone.

Some fluctuations of serum cholinesterase[4] occurred, with a tendency toward depression. For instance, there was a fall from about 110 to 80 units in the case pictured in chart 1. This did not appear to be very significant, however, when compared with the great depression that can be obtained with anticholinesterases such as diisopropyl fluorophosphate. No appreciable change in basal metabolic rate occurred. Serum potassium and sodium levels showed no notable change. Unfortunately, we were not equipped for urinary potassium determinations, which might have been of greater interest than the relatively stable serum levels. All patients, with the exception of one with disseminated lupus erythematosus, had feelings of well-being and mild euphoria, and with the same exception all showed prompt water retention and weight gain. Only one patient had a significant rise in blood pressure.

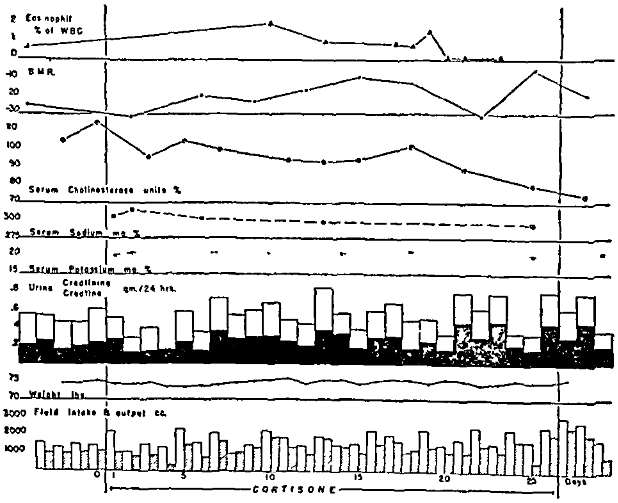

Chart 1 (case 1).—Absence of significant variations in sodium and potassium levels, although the myotonic response entirely disappeared.

It should be pointed out that because of the slow absorption of cortisone acetate, the effects of the hormone take some time, often five or six days, to become manifest. A similar period is required for the effects to wear off when administration is discontinued. Pituitary adrenocorticotropic hormone, on the other hand, works in a period of several hours.

SPECIFIC RESULTS

Dystrophia Myotonica.—Both patients were given 200 mg. of cortisone the first day and 100 mg. on each successive day. This was administered in depots of 50 mg. each. Aside from the general responses noted above, the most striking change was the complete abolition of the myotonic response.

Case 1.—A. C., a housewife aged 39, was admitted with the complaints of progressive wasting and weakness and difficulty of relaxation of all extremities for some six years prior to admission. Her speech had been impaired for the same period. She had been bedridden for about one year. One sister had the same illness, and one brother had voice changes but no other symptoms.

On examination there was marked muscle wasting (weight 76 pounds [34.5 Kg.]), most marked in the sternocleidomastoid, trapezius and shoulder girdle muscles and in the forearms and hands. The patient had a myopathic facies, opacity in the lenses of both eyes, dysarthria and a weak nasal voice. A typical myotonic response was obtained on percussion of the thenar eminence or the tongue. The electromyogram showed characteristic repetitive potentials on insertion of a concentric needle electrode, and these lasted from 70 to 120 seconds in the thenar eminences and in the tongue. The various biochemical and other changes are pictured in chart 1.

Within nine days after commencement of therapy no myotonic response could be noted either clinically or in the electromyogram. The dysphonia had improved until the patient's voice was audible at 30 feet (9 meters), whereas on admission she could be heard no farther than 5 feet (1.5 meters). She claimed that she had increased strength and could carry out certain tasks not previously possible, but no great objective change in muscle power could be made out during the 26 day period of therapy. The rather marked creatinuria was, if anything, intensified during treatment. The myotonia was beginning to return five days after the use of cortisone was discontinued.

Case 2.—G. P., a 32 year old woman, complained of inability to let go of objects in her hand. This had lasted for a period of seven months prior to admission. She had also had progressive difficulty in swallowing and nasal speech for the same period. The siblings of the family had the following afflictions: One man aged 27 had cataracts, nasal speech, testicular atrophy and myotonia; one woman aged 23 had nasal speech and myotonia; one man aged 43 had cataracts and premature baldness, and one woman, age unknown, had myotonia. Two siblings were not examined.

The patient on examination showed slow relaxation of the hand grip and myotonic oscillatory responses on insertion of a concentric needle electrode into the thenar musculature. She had a myotonic contraction on tapping the thenar muscles and the tongue.

All the myotonic phenomena had disappeared in this patient by the eighth day of treatment.

The second patient did not have such profound weakness and wasting as the first, but each felt some increase in muscular power. This was demonstrated clinically by weight and pulley tests. Both patients gained considerably in weight. It is of interest that the biopsy wound in the latter patient was as fresh and unhealed at the end of 12 days' therapy as it was on the day of incision. It healed normally when the administration of cortisone was discontinued.

This abolition of the myotonic response corresponds to the action of the 11-desoxycorticoids (mineral corticoids), as noted by Harvey and Brown[5] in myotonic goats. Since the speech defect did not disappear along with the myotonia, it is probable that it is due to muscle weakness and not to myotonia.

Disseminated Lupus Erythematosus.—Case 3.—O. K., a 20 year old female stenographer, had been in good health until six weeks prior to admission. At that time she began to complain of rapidly progressive weakness and stiffness of the upper and lower limbs, more marked proximally. There was edema of the face, the involved muscles and the overlying subcutaneous tissue. She had noted a red rash over the face, nose, ears and chest. On examination she showed extreme difficulty in talking and swallowing and had to be fed by tube. There was an erythematous, scaly eruption over the upper eyelids, cheek, bridge of the nose, ears, area of the chest, elbows, hands and feet. There was a tachycardia (pulse rate 160 a minute), with some cardiac enlargement. Weakness of the shoulder and hip muscles was so profound that she could not lift her arms or legs from the bed. All involved muscles were swollen and felt "boggy" but were not especially tender on pressure. Early contractures were developing, however. There was fever (temperature 101 to 103 F.) and an elevated sedimentation rate. The picture then was one of a constitutional reaction plus an acute dystrophic process in the voluntary muscles. Muscle biopsy disclosed the appearance of a diffuse myositis.

[4] Odom, G.; Russel, C. K., and McEachern, D.: Myogram, Blood Cholinesterase and Effect of Prostigmine in Myasthenia Gravis and Progressive Muscular Atrophy, Brain 66: 1-17 (March) 1943.

[5] Brown, G. L., and Harvey, A. M.: Congenital Myotonia in the Goat, Brain 62: 341-363 (Dec.) 1939.

This patient received 200 mg. of cortisone daily for nine days. On the eighth day a profound diuresis began, and on the tenth day the use of cortisone was discontinued and pituitary adrenocorticotropic hormone therapy was initiated in daily doses of 160 mg. This was given in four divided doses. On the sixth day of pituitary adrenocorticotropic hormone therapy, all clinical signs of intracellular excess fluid had disappeared and the weight drop had reached its maximum. The patient then began to retain fluid again, and the moderate weight increase can be seen in chart 2. At no time did the muscles regain their original "boggy" feel. No increase in muscle strength could be detected. At no time was she able to lift her head from the pillow, and she had to be fed by tube until the time of her discharge. The basal metabolic rate of this patient fell, as might be expected from the weight loss. Creatine excretion was lowered to some extent during treatment. The pulse rate fell from 160 to an average of 96 a minute, and the body temperature fell from 101 F. to a normal base line. The skin lesions became less marked. There was thus a marked improvement in the constitutional symptoms but none in the acute dystrophic process in the skeletal muscles, although hormone therapy was continued for a total of 35 days. This patient has since died.

Case 4.—A. S., a female journalist aged 35, was well until July 1948, two years before admission, when there was rapid onset of pain and swelling in the joints of fingers, wrists and ankles. Sulfonamides were administered, and the patient recovered in August 1949. There was a recurrence, along with fever and a red scaly eruption over the extensor surfaces of the legs, elbows and wrists, with generalized aching throughout the body. This was followed by a scaly red rash over the nose and the malar regions.

From January to April 1950, the patient was treated with desoxycorticosterone acetate (percorten®), 5 mg., followed immediately by intravenous injections of 1 Gm. of ascorbic acid in 10 per cent solution. This treatment was maintained with 4 injections a week, without improvement. In April pregnenetriolone acetate (prenolon®), 200 mg., and salicylates, 40 grains (2.59 Gm.), were given daily, without improvement. She was hospitalized from April 12 to April 22, and at this time had several febrile episodes. No lupus cells were found on sternal puncture or in the buffy coat of the blood. The condition continued and her weight fell from 116 to 96 pounds (52.6 to 43.5 Kg.). At the time of admission to our hospital, on June 4, 1950, it was found that she had been unable to walk since April 22 because of muscular weakness.

Examination showed a systolic gallop rhythm and a questionable pericardial friction rub. The blood pressure was 110 systolic and 70 diastolic. The pulse rate was 100 to 110. The lymph nodes were palpable in the neck, axilla and groin, and they were tender. There was generalized skin and muscle tenderness, and the skin seemed slightly indurated. There was bilateral foot drop with achilles tendon contracture. The extensor hallucis longus, tibialis anticus, extensor digitorum communis groups in the foot and the gluteus muscles at the hips could not move against gravity. There was also severe weakness of the iliopsoas, quadriceps, deltoid, supraspinatus and triceps muscles. All muscles were tender to palpation. The patient was bedridden.

The use of cortisone acetate was started in doses of 200 mg. the first day and 100 mg. daily thereafter. This was administered in depots of 50 mg. each. By the fifth day most of the pain had disappeared, the patient was afebrile, and, unlike the case 3 results, the more severely affected muscles had recovered power against gravity. By the seventh day muscle power against resistance had almost reached a normal level. On the evening of the seventh day the patient walked for the first time in almost four months. The rash now has almost completely disappeared. At the time of writing (ninth day of therapy), she is starting to ascend and descend stairs. Moderate contractures at the various joints have disappeared. In this instance both the constitutional reaction and the profound muscular weakness disappeared with incredible rapidity, and the patient gained 7½ pounds (3.43 Kg.) in the five days preceding the draft of this report.

These two cases should emphasize the facts that muscle changes may be predominant in this little understood condition and that skin changes and other phenomena may be mere highlights pointing the way to diagnosis.

Juvenile Muscular Dystrophy with Collagen Changes.—Case 5.—J. S., aged 29, gave a history of progressive weakness and wasting of the arms and legs, beginning in early childhood and becoming prominent at 13 years of age. He had been unable to stand or sit unsupported for two or three years. For the past four years he had been unable to flex the neck or spine and was "stiff as a poker." This was apparently due to ligamentous changes or to muscle contractures and not to bony ankylosis. Roentgenograms showed no arthritic changes. No siblings were similarly affected.

Examination showed generalized muscular wasting, without involvement of the intrinsic musculature of the hands and feet. There were flexion contractures of the elbows and knees and fixation of the spine in hyperextension. There was no myotonia. The entire picture was quite different from pseudohypertrophic muscular dystrophy.

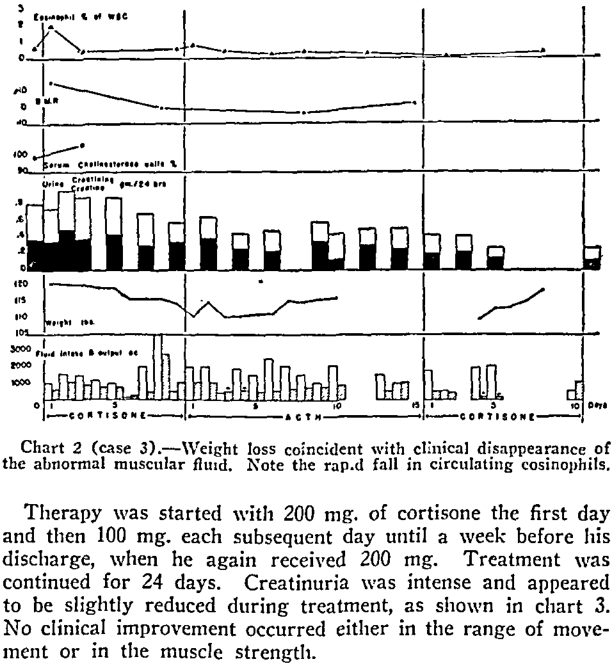

Chart 2 (case 3).—Weight loss coincident with clinical disappearance of the abnormal muscular fluid. Note the rapid fall in circulating eosinophils.

Therapy was started with 200 mg. of cortisone the first day and then 100 mg. each subsequent day until a week before his discharge, when he again received 200 mg. Treatment was continued for 24 days. Creatinuria was intense and appeared to be slightly reduced during treatment, as shown in chart 3. No clinical improvement occurred either in the range of movement or in the muscle strength.

Theoretically this seemed to be our most promising case for trial of cortisone, but perhaps the condition was too advanced.

Progressive Muscular Atrophy—Motor Neuron Disease.—Case 6.—E. F., a 48 year old nurse, complained of progressive difficulty in swallowing and articulation for one year. Five months before admission she noticed wasting and weakness of the muscles of the hands and, more recently, those of the thigh. Involuntary twitchings had been noticed in these muscles for five months.

On examination it was found that the mouth could not be voluntarily closed and drooled saliva. The eyes could not be closed voluntarily but could close reflexly. The tongue could not be projected, and it showed gross wasting and fasciculation. On attempted phonation, there was no movement of the soft palate or pharynx. The jaw jerk was greatly increased. There was weakness and fasciculation of both forearm and thigh muscles, as well as profound wasting of the intrinsic musculature of the hands. The abdominal reflexes were absent, the deep tendon reflexes increased and the right plantar response equivocal.

At that time the patient presented the terminal stages of motor neuron disease, with both bulbar and pseudobulbar palsy and amyotrophic lateral sclerosis.

During the administration of cortisone no improvement was noted, although a daily dosage of 200 mg. in four divided depots was maintained. Fasciculations were so variable that it cannot be stated that cortisone affected them.

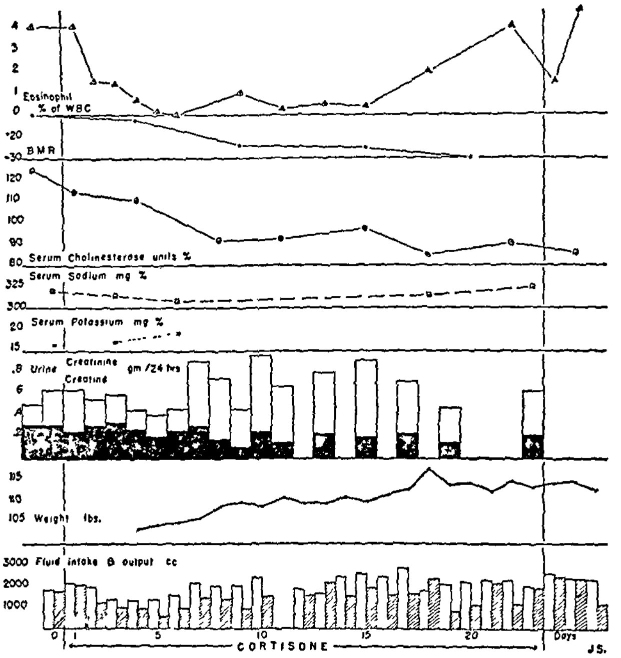

Chart 3 (case 5).—Response to cortisone therapy demonstrated by the eosinophil fall and weight gain of the patient. No improvement in the muscular condition could, however, be demonstrated.

The failure to affect the course of this disorder is in agreement with the results published by others.[6] It is of interest that the patient had unexplained eosinophilia and low grade fever, which persisted during cortisone administration.

Case 7.—L. B., a 38 year old housewife, had a history of progressive weakness and stiffness of the legs and arms, particularly of the hands, for approximately 14 months. She, like patient E. F. (case 6), had had difficulty in speech and swallowing for about ten months.

Examination disclosed wasting and fasciculations of the interosseus, quadriceps and tongue muscles. The deep tendon reflexes were increased, and the plantar responses were extensor. Biopsy demonstrated denervation compatible with motor neuron disease.

The patient received 200 mg. of cortisone the first day and 100 mg. daily thereafter for a total of 21 days. Aside from a mild euphoria, no clinical improvement could be detected.

Myasthenia Gravis.—Case 8.—G. H., a 29 year old truck driver, had noticed progressive weakness and fatigue of the facial and neck muscles, so that his head occasionally fell backward in the morning on rising. He also had difficulty in chewing, swallowing and speaking, and he tired rapidly. He gave a history of some weakness and fatigue of the arms and legs for the past year. The response to neostigmine was good.

Examination showed marked weakness of the facial, masticatory and pharyngeal musculature. There was also marked weakness of the neck muscles and the muscles of the shoulder girdle, most marked in the deltoids. He had a lobulated neoplasm in the anterior mediastinum, visualized on roentgen examination. Prior to the initiation of cortisone therapy, this patient could carry on fairly normal activities with 180 mg. of neostigmine bromide a day.

The patient suffered a severe exacerbation of his myasthenic symptoms while under cortisone therapy. This was so marked that he could not swallow or chew his food or maintain his head erect, even while receiving 270 mg. of neostigmine bromide. At this stage, the sixth day of administration of 100 mg. of cortisone daily, the administration of cortisone was stopped. The patient gradually returned to his preadministration level over a 10 day period. He did not appear to rebound to a state exceeding his precortisone level of power or stamina, as was observed by Torda and Wolff[7] in their studies with pituitary adrenocorticotropic hormone.

All these results may be important in terms of the mechanism of myasthenia gravis, even though they do not offer immediate therapeutic prospects. No decrease in size of the thymic shadow could be demonstrated by roentgen examination at the height of therapy, such as was reported in one case of Soffer and his associates.[8] Adrenal cortex hormones are known to shrink the thymus,[9] but it is only a matter of speculation as to what part this might play in the disease mechanism. The response is demonstrated in chart 4.

Myopathy Appearing After Menopause.—We have coined the term "menopausal myopathy" to describe proximal muscular weakness involving the pelvic and shoulder girdles which appears in the years following the menopause, or the climacteric. Patients with menopausal myopathy have great difficulty in climbing stairs or in rising from a chair, and are subject to unpredictable falls due to sudden giving away of the legs. This condition can be easily missed and may be attributed to the general enfeeblement of age. Strength in the hands and feet remains great, however, and, what is more, the condition appears to be reversible. No wasting of the affected muscles can be demonstrated, as a rule. Following is a typical case.

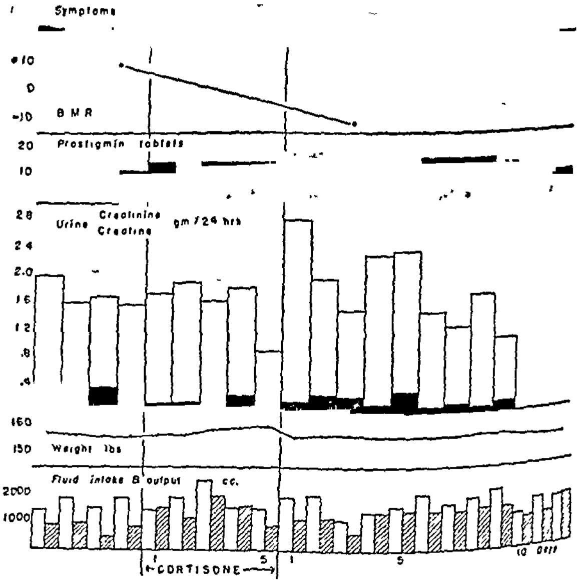

Chart 4 (case 8).—Increase in severity of symptoms in the patient with myasthenia gravis at the fourth to fifth day after cortisone administration. Note the exacerbation occurred in spite of increased neostigmine administration.

[9] McEachern, D.: The Thymus in Relation to Myasthenia Gravis, Medicine 22: 1-25 (Feb.) 1943.

Case 9.—R. P., a housewife aged 53, complained of slowly progressive weakness of the lower limbs, more marked on the left side. Symptoms began several months after her menopause, three years prior to admission. She had extreme difficulty in rising from a sitting position and in climbing stairs. Previously, she had undergone surgical removal of both breasts for bilateral cystic mastitis.

Examination showed no obvious muscular atrophy, but normal muscle resiliency was absent on palpation. A myopathic progress was confirmed by biopsy of the thigh muscle. There was a marked degree of weakness of the quadriceps, gluteus and adductor muscles. Some weakness was also present in the shoulder girdle muscles, the distal musculature being relatively spared. Deep tendon reflexes were absent in the lower extremities.

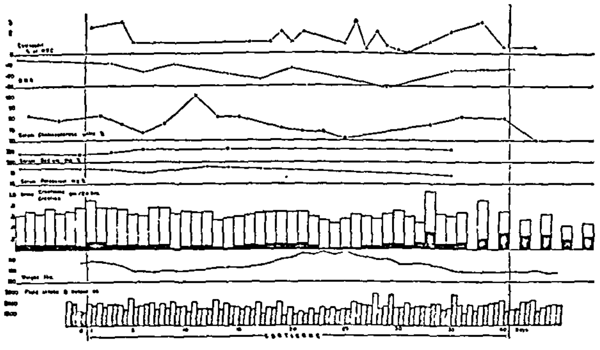

Chart 5 (case 9).—Weight variations in this patient as the cortisone dosage varied (detailed dosage schedule is given in text). This patient improved markedly on cortisone administration.

On admission this patient could climb only five steps in 20 seconds, using her hands on the railing. After cortisone therapy she could climb 40 steps in the same time without the use of her hands. She received 200 mg. of cortisone the first day, in four depots, and then 100 mg. a day in two depots until the eighteenth day. The dose was then increased to 200 mg. a day until the twenty-third day when, owing to the pronounced weight gain shown in chart 5, the dosage was decreased to 50 mg. daily for the remainder of the course of treatment. She voluntarily drew attention to the fact that her mastectomy scars had softened. Six days after the cholesterol control period was instituted, muscular weakness returned, and in the following weeks she had several bad falls. We are now trying to work out a maintenance dosage.

Case 10.—B. M., a housewife aged 59, noted the onset of her difficulty in climbing stairs and rising from a sitting position approximately six months after her menopause, in 1940. She became bedridden. Wheat germ oil was added to her diet in 1942, with such remarkable results for three or four years that the patient led an active life. Since 1947 she had again deteriorated, although use of wheat germ oil medication was continued. At the time of admission she could no longer manage stairs and could walk only with a cane. She also had episodes of sudden falls without warning.

On examination, the muscles involved were of soft, fluctuant consistency, and there was marked weakness of the proximal girdle musculature, severest in the lower extremities. Again, the distal musculature was relatively spared.

This patient received 200 mg. of cortisone the first day in four depots and 100 mg. daily thereafter. After eight days she showed a threefold increase in power on weight and pulley tests and was able to rise from a chair and climb stairs without the aid of her arms for the first time in eight years. This patient also suffered from mild gouty arthritis, and she became free of pain during the administration of cortisone. The pain returned during the cholesterol control period.

Case 11.—R. McG., a 58 year old farmer, first noted weakness of the legs eight months prior to admission. This was most noticeable in bending to pick up objects, in sitting or rising from chairs and in climbing stairs. He also had great difficulty in rising from a lying position and did so by turning on his abdomen and climbing up his legs with his hands. Five months before admission he noted weakness of his arms but not of his hands. He had difficulty in lifting objects, in getting into and out of clothing and, finally, in shaving and combing his hair.

On examination flexion at the hips was limited to passive movement at 70 degrees bilaterally. There was moderate weakness of the supraspinatus, infraspinatus, teres, deltoid, triceps and biceps muscles. There was no weakness of the wrist extensors or flexors or of the intrinsic hand musculature. There was marked weakness of the iliopsoas and gluteus muscles, and the legs could not be elevated from the bed. There was moderate weakness of the quadriceps, hamstring and adductor muscles. Occasionally gross twitchings of the muscles occurred with movement. They led to the suspicion of motor neuron disease but appeared to be more in the nature of uncoordinated muscular contraction. There were no pyramidal tract signs.

This patient received 200 mg. of cortisone the first day and 100 mg. daily thereafter in depots of 50 mg. for a total of 21 days. He improved markedly, and for the last seven days before discharge he could lift his legs voluntarily 30 consecutive times from the bed. This patient had an almost normal creatine: creatinine ratio, and this was unchanged during cortisone administration. The condition appears to be another example of proximal myopathy of the climacteric period. We are at present attempting to establish a maintenance dosage.

Case 12.—E. V., a 58 year old laborer, was admitted with an eight month history of progressive weakness of the pelvic and the shoulder girdle muscles. He received cortisone, 200 mg. the first day, and 100 mg. each successive day. No improvement could be ascertained. A definite myopathic involvement of the quadriceps femoris was revealed by biopsy.

All patients gained weight and had diuresis during the control period. Myopathic changes in all cases were confirmed by biopsy.

Increasing muscular weakness began to reappear in both women and in one man about five days after the administration of cortisone was stopped, but improvement set in again when treatment was reestablished.

It is of interest that out of the large number of patients (107) with neuromuscular diseases that we have treated with wheat germ oil[10] in the past, improvement has been noted in the small group with menopausal myopathy.[11] They have also had relapses when use of wheat germ oil has been discontinued for several months. This brings up the question whether wheat germ may not contain building blocks for steroid hormones.

SUMMARY

Twelve patients with various neuromuscular disorders have been treated with cortisone.

In two patients with dystrophia myotonica the myotonic response was completely abolished by cortisone therapy *during the period of treatment*. Improvement in the dystrophic state was doubtful.

One patient with generalized lupus erythematosus and an acute dystrophic process in the skeletal muscles showed marked improvement of the constitutional state. There was, however, no improvement in muscle power. Another patient, with less severe manifestations of this disorder, improved dramatically, and muscle power returned to normal.

One patient with juvenile muscular dystrophy with collagen changes and two patients with motor neuron disease were unimproved by cortisone therapy.

One patient with myasthenia gravis was made worse by cortisone therapy but returned to his previous status

on discontinuance of treatment. This observation may be important in terms of the mechanism of myasthenia gravis.

Two women with menopausal muscular myopathy showed decided improvement while being treated with cortisone. One man also improved on the same therapy and dosage, but another man failed to improve. This condition in women previously had been found to respond to wheat germ oil therapy but with a longer time lag.

CAUSES OF FEAR AMONG OBSTETRIC PATIENTS

Chairman's Address

JAMES RAMSDELL BLOSS, M.D.
Huntington, W. Va.

It is a great privilege to have for review almost a half century of activity in any field of human endeavor. One of a previous professional generation may be forgiven if he views with amazement and awe his temerity in having attempted to undertake the responsibilities that he had to assume with an armamentarium so primitive when compared with that at his command today. As one who has been a part of those years of matchless professional progress and scientific accomplishments (even though in such a minor role as has your chairman), I wish to present some thoughts for consideration with the hope that they may have something of constructive value to commend them. Years of experience with a passion for the detailed clinical observation of each patient as an individual entity will of necessity develop a physician's diagnostic acumen, his ideas and opinions and the accuracy of his considered final judgments and therapeutic endeavors.

The wife of a physician had been delivered by one of America's well known obstetricians. For a subsequent delivery he referred her to one of the most prominent protagonists of the psychosomatic school of obstetric practice. Some months after her second delivery she remarked to her former attendant, "I had actual scientific care, but if I should choose my obstetrician I would prefer sympathy and human kindness first and scientific care second." A thought to give one pause, is it not? May it not be possible that those who have been endeavoring to teach undergraduates, interns, residents and postgraduate students are neglecting one of the basic fundamentals of medical training? At times one wonders whether there is not a great need to instill in medical leaders the ability to teach and practice the art as well as the science of medicine.

FEARS WITH PSYCHOLOGIC BASIS

With this thought in mind, humbly making my obeisance to the psychosomaticists of my specialty, it seems timely and germane to discuss some of the causes of fear among obstetric patients. The importance of such a discussion has been particularly impressed on me in recent years by the experiences of my associates and me in the antepartum care of our patients. In the women's magazines the numerous articles dealing with the dangers contingent on the discovery that a prospective mother has Rh-negative blood or the utopian claims for the advantage of continuous caudal anesthesia over saddle block and other technics of analgesia and anesthesia, seem to me to have done harm in that the mental perturbation they have caused among pregnant women is much greater than any good they have accomplished.

The experiences of life over the years reveal that most of the fears which beset everyone from time to time are needless. Many years of obstetric practice convinces me that one of the most important accomplishments of the obstetrician is his ability so to guide his parturient patient through her antepartum period that she shall approach the time of her delivery unafraid, rather "as one who wraps the drapery of his couch about him and lies down to pleasant dreams." The practice of the obstetric art requires much time and infinite patience, and thrice blest is he who has been so fortunate as to have also had previous training and experience in clinical psychiatry. It might be well to require that a certain amount of the time of the obstetric and gynecologic residency be given to this branch of medical study as is done in pathology in relation to the specialty.

Seldom does the obstetrician see cases of such severe antepartum mental disturbance that a psychosis is diagnosed and treatment instituted. Most frequently this state of affairs goes unrecognized and untreated, yet it would seem hardly possible for such experiences not to produce some effect on the average patient.

In no field of my medical experience has it been noted that the home environment and the influence of parental guidance of children is so evident as in the observation of women during the period of professional contact as their obstetric attendant. Prolonged indulgence and protection by unwise parents results in an incapacity to face realities, to realize and evaluate personal responsibility or to make decisions. They are parasites in that they live on the mental and moral strength of others. Naturally, persons in this category are capable of only poor mental adjustment to the unsatisfactory situations and conditions of life and are prone to have a negligible ability for endurance or for making personal sacrifices.

In contrast there are other persons who face all the problems of life unafraid. They solve and overcome the issues, whether great or small. They adapt themselves to meeting sorrow and joy, disappointment, accomplishment, the anxiety and pain of illness, poverty or wealth on an even mental keel. These persons are psychologically evolved or mentally mature.

If one has a clear understanding of these psychologic factors it will aid immeasurably in the approach to and the solution of the maternity patients' problems in the realm of fear. The next important point is that the obstetrician must secure the most complete confidence of his clientele. After this is achieved it is then usually easy for these parturient women to express their mental doubts and fears. With this accomplished the outcome of their struggle to overcome the unhappy mental state is far less in jeopardy. To the patient these fears are very real, and it is a grave error in therapeutic strategy to belittle them or to permit the patient to feel that one is not giving serious and considered thought to their disturbing problems. By all means avoid giving the impression that one regards their fears as ridiculous.

To catalogue all the fears which have been revealed to me by parturient women during the years I have spent in the practice of obstetrics would be an intermina-

---

Read before the Section on Obstetrics and Gynecology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

ble undertaking. Probably among the most frequently encountered may be mentioned that they will lose their willowy figures; that they may lose their sex attraction or function; that their physical appearance during pregnancy will affect the husband's affection and future love for them; that pregnancy may occur at the climacteric period and that there is increased danger of complications when they are past 35 years of age; that if they nurse their offspring the effect on their streamlined appearance will be disastrous, to say nothing of tying them down and interfering with their social activities. In this group should be included the fears of having a deformed or mentally defective infant because of an unsuccessful attempt to produce an abortion, of marking the unborn infant by a fright or shock during pregnancy and of the influence of heredity. This bizarre group of fears is extremely real to patients as individuals and is of important significance in producing mental and emotional conflicts.

BASIC CONFLICTS

It will be of assistance in the care and management of this type of parturient women for one to have some understanding of what these psychic conflicts are and of the mechanism of their development. Despite women's statements to the contrary and their efforts to conceal it from those about them, experienced clinicians, particularly those of the obstetric fraternity, believe that since the dawn of creation the dominant basic feminine instinct is that of reproduction. It is truly primal in all living creatures and in many is more powerful than that for the preservation of life itself. In those women who deny this there is definitely a reason, possibly a subconscious one, which is not in harmony with the idea of motherhood. The woman may be, from environment and training, vain or selfish. She does not wish to make the needful personal adjustments for fear that she may lose the grace and charm which she may be convinced are so outstandingly hers or that she may have to forego the luxury of personal physical comforts which she may be accustomed to enjoy. With such strong and antagonistic feelings one may readily understand how there does develop a psychic conflict, at times of tempestuous character, with the primal maternal instinct. The mentally mature or psychologically evolved woman will, with little or no help, reason out these situations and satisfactorily adjust herself to making all sacrifices of convenience and personal luxuries for the accomplishment and joy of motherhood. With the unevolved person the problem is much more complicated and trying for all concerned. Only experience and a genuine interest in the welfare of his patient can guide the understanding obstetrician.

There is no accurate method for securing a dependable statistical study on the frequency of attempted abortion. Certainly this must be much commoner than is ordinarily realized. It is generally the fear of having a physically or mentally abnormal child which is revealed to the physician in his professional capacity. Careful psychologic study over many years leads me to the conclusion that it is not so much the stated fear of the results of attempted abortion as it is the desire to get the burden of mental guilt off their conscience and to learn the medical attendant's view of the spiritual gravity of their sinful desire in the attempted destruction of the unborn child.

Over the years I have seen no instance in which an unsuccessfully attempted abortion has been followed by the birth of a physically abnormal or deformed child. Many of the resultant children are now adults, and in them I have noted no mental abnormalities which might not much more appropriately be attributed to their inherited familial genes and chromosomes. Certainly there has been no congenital absence of gray matter due to the unsuccessful outcome of an attempt to produce an abortion. A kind heart, an understanding experience and something approaching at least a speaking acquaintanceship with the Almighty will be needed to guide one in answering these unexpressed but momentous questions of spiritual guilt.

The fear of death and the development of complications is another of the more frequent causes of mental unrest in the antepartum period. This fear of death and disease is not an uncommon one for most persons to have, nor equally so is reticence in confessing such a fear. It does not occur to the relatives and close friends of a pregnant woman, as they gossip and recount the unhappy experiences of other women during labor, that she may be having such a difficult mental struggle.

Everyone has had to deal with such situations and at times has been at wit's end as to how to solve the problem. Personally it has proved most satisfactory to discuss these experiences as frankly as may be possible and to point out that countless women have come safely through the ordeal of motherhood. Then call attention to all the safeguards employed by the modern obstetrician to forestall such occurrences and to the special care being exercised in her case to prevent the possibility of such a catastrophe.

Even in this enlightened day the fear of "marking" the unborn child still exists. The witnessing of some accident, being bitten by pets, seeing or being frightened by reptiles and unreasonable cravings for unseasonable foods are still credited as being infallible etiological factors in such occurrences. The psychosomatic approach handles these patients most satisfactorily.

FEARS WITH LEGITIMATE BASIS

Some fears are without the realm of those just discussed, in that there is a basically legitimate reason for them. In this group is the question of possible transmission of syphilitic infection to the offspring. In spite of all the educational efforts being made, I am still having to answer questions on the possibility and probability of such a congenital misfortune. Thanks to the scientific advances in today's therapy of syphilitic infection, one may with confidence assure antepartum patients that this may be erased from the list of their fears.

A word of caution in regard to the interpretation of the routine standard study of the mother's blood for syphilitic infection may not be amiss. In a few rare instances faintly positive reactions may be found during pregnancy in hypoendocrine women. The reaction is usually approximately similar to that noted in an inadequately treated patient in the day of mercury, bismuth and arsenical therapy. Metabolic studies will reveal a minus reading. It will be noted also that the positive serologic reaction disappears a few days after delivery. Further, the blood of the infants will not give this positive reaction. Many years ago a near fatal outcome in administering antisyphilitic therapy to two such patients was a most harrowing experience.

A half century ago, when pregnancy occurred in a person with tuberculosis, diabetes or a cardiac impairment, it was believed that the pregnancy was of primary concern and that the preexisting condition was to be considered as a complication. As time passed this view has changed, and today the obstetrician realizes that the realm of his professional activity is the supervision of the pregnancy as a complication of the preexisting physical impairment of the person. In the management of such patients it is of imperative importance that the closest cooperation of an experienced internist be sought. Few obstetricians will consider themselves professionally competent to guide and direct the treatment of the primarily existing illness. The responsibility for the parturient phase of such a situation seems sufficient for one person to assume.

As I look back over the years nothing is more striking than the changed attitude in regard to pregnancy occurring in the woman ill with pulmonary tuberculosis. Naturally this as a cause of fear is understandable. Formerly it was generally believed that pregnancy allowed to continue practically sounded the death knell for the patient. Thirty or forty years ago physicians were advised that pregnancy complicated by an acute, or even an arrested and quiescent, tubercular infection should promptly be terminated by therapeutic abortion. The observation that among those who refused this drastic therapy a certain number actually seemed to be improved led some obstetricians to advise against this course and to insist on completion of the pregnancy with redoubled efforts in the treatment of the tubercular infection with rest, sunshine, fresh air, food and such tonic therapy as might seem indicated. The results were illuminating and the outcome eminently more satisfactory than those with the previous methods of handling such patients.

Today the scientific management of the tuberculous patient has, to a pronounced degree, removed the fear of pregnancy as a complication. With the development and skilled employment of collapse therapy and the rigid adherence to her hygienic regimen, the patient goes through her pregnancy and delivery with no detectable injury or exacerbation of her tubercular infection. I believe that one of the most outstanding accomplishments in the obstetric management of these patients is the employment of the spinal block method for securing relief from the pain of delivery and the use of the less depressing technics for securing analgesia during labor.

Incidentally, it seems advisable to emphasize most careful examination of the chest of the pregnant woman. Recent surveys indicate that a much larger number of persons have tubercular pulmonary involvement than has been suspected. Studies reported statistically indicate that pregnant women do not present a variation in mortality or morbidity from that in a similar age group of an equal number of nonpregnant women who are tuberculous. Over the past 20 years my experience is in support of this conclusion.

Another outstanding accomplishment of modern medicine is in the technical handling of the diabetic patient when pregnancy occurs as a complication of the preexisting disease. Until the discovery of insulin and until experience was gained in controlling disturbances of metabolism in the diabetic person, the prognosis for these pregnancies was most discouraging.

When one is undertaking the responsibility of caring for a pregnant patient with glycosuria it is of primary importance to determine whether the patient has true diabetes mellitus. In the preinsulin period some clinicians believed that diabetes was responsible, to some extent at least, as a cause of sterility, the frequency of abortions, prematurity, stillbirths and anatomic abnormalities. Certainly the present day therapy for diabetic patients seems to have increased their fertility. My clinical experience with pregnancy as a complication of true diabetes mellitus has not been sufficiently extensive to permit the formulation of a definite opinion concerning the value of the hormonal therapeutic approach to the handling of these patients. Possibly it is not too much to hope that further research in the realm of endocrinology may eventually open this door.

In my years of obstetric prognostication I never have felt more helpless a prophet than when I find myself confronted with pregnancy complicating cardiac disease. At times one observes patients going apparently uninjured through a number of pregnancies and labors although they have valvular lesions which should by the ordinary rules confine them to bed even if they were not pregnant. Others with a seemingly much less serious condition will prove to have no cardiac reserve. Here professional judgment and skill are taxed to the utmost to carry them successfully through their pregnancy. There is no standardized therapy for these patients. Each must be truly individualized and handled as such. Few obstetricians have had a sufficiently extensive cardiologic experience to justify their assumption of such a dual professional role.

It is difficult to understand how a woman with preexisting cardiac disease could go through pregnancy and labor without being injured. The danger of pregnancy is decidedly increased in those who have had previous episodes of cardiac decompensation, regardless of whether they were at that time pregnant or nonpregnant. In the care of these cardiac parturients the most painstaking medical supervision is necessary. With this provided, it has not in my experience been deemed necessary to abort any of them therapeutically.

The problem of labor for the cardiac parturient was most perplexing in the days of inhalation anesthesia. Today with technics of analgesia, and particularly of spinal block and infiltration anesthesia, so scientifically perfected, labor has lost much of the danger formerly present. In my opinion certain of these patients should be delivered electively by abdominal section under spinal or local infiltration anesthesia. This has seemed especially advisable when the patient has severe mitral stenosis, aortic insufficiency or a combination of the two.

THE RH FACTOR

Probably all physicians have been harassed almost beyond endurance concerning Rh-negative blood. The unfavorable publicity noted in most of the articles concerning this condition which have appeared in the magazines of wide lay circulation have been of great harm to the peace of mind not only of parturient women but also of the recently married and of those contemplating matrimony. It is truly remarkable how many questions of a "now suppose" type arise under stimulus of the fear engendered by these magazine articles, when the Rh-negative condition is found to exist.

When the Rh factor was discovered and announced to the members of the medical profession I suspect that most of us felt about as the mathematicians must have, when Professor Einstein promulgated his theory of relativity. Since then it has become possible for these serologic tests to be made for the investigation of this subject at a cost which is economically practical. As a result of widespread and intensified study by many workers in this field, one may reply to questions of these persons about the Rh factor with the assurance that accumulating investigation and clinical experience make it possible to give a somewhat more intelligent answer and not a more or less oracular guess.

On July 1, 1946 I began a study of the Rh factor. At first the laboratory study of the Rh status of patients was made only when there was a history of previous abortion, prematurity or stillbirths or of previously received transfusions. This plan was followed until Jan. 1, 1948. Since that time the Rh factor has been checked in all women seeking obstetric service who had not been under my supervision subsequent to July 1, 1946. This is now done routinely whether or not the history reveals any of the suggestive leads previously mentioned. This study gave the following information: There was a total of 1,354 (85.86 per cent) Rh-positive and 223 (14.14 per cent) Rh-negative persons. Deliveries for the years 1947, 1948 and 1949 totaled 1,918. The deliveries for the final six months of 1946 were not included, because it was not practicable to study the Rh factor for those mothers first seen previous to July 1, 1946.

Two erythroblastotic infants were lost. One was stillborn; the second lived 36 hours and was atelectatic. The titer of this mother when last determined before the birth of the child was 1:680. Autopsy showed that both these infants were erythroblastotic. A third infant with an erythroblast count of 30 per cent at birth responded to transfusions and now is apparently a normally healthy child aged 2 years.

These studies reveal a number of facts which are not only interesting but of much assistance in discussing these matters with patients. First, a certain number of the husbands may be Rh negative. Three of the 99 Rh-negative parturients of 1949 had Rh-negative mates. Then one must bear in mind that a high percentage of Rh-positive men are heterozygous and will father Rh-negative offspring. The fact that many, possibly the majority, of Rh-negative women may bear two or even more Rh-positive infants before developing a sufficient immunization to produce an abortion or an erythroblastotic infant is to be borne in mind. One must not lose sight of the small mathematical probability of Rh-factor mismatings. It is possibly less than 0.5 per cent. As a final addition to the psychosomatic armamentarium for combating the fears of distraught parturients, the knowledge acquired in this particular field of hematological research enables one to give much encouragement for the survival of erythroblastotic infants by replacement transfusion of carefully selected blood.

It is not out of order to reemphasize the warning of the transfusion danger of giving Rh-positive blood to an Rh-negative person. Much can be done to lower the incidence of sensitization of Rh-negative females, whether infants or adults, by firm insistence that only blood of compatible Rh-negative donors be employed for needed transfusions.

The problem of determining what course to pursue in the delivery of these parturients must of necessity be individualized. When careful study reveals that the mother is not immunized or, if so, that the titer is low and the history does not reveal either a transfusion with Rh-positive blood or a previous erythroblastotic pregnancy, I do not consider it advisable to induce premature labor. My results under such conditions have been most satisfactory by awaiting the normal onset of labor. When conditions are the reverse, it seems advisable to terminate the pregnancy prematurely either by induction and vaginal delivery or by abdominal section, in the interest of the infant and its survival. A word of caution in connection with the decision to terminate the pregnancy prematurely. Do not terminate the pregnancy so far in advance of maturity that the child dies because of immaturity rather than erythroblastosis.

As a result of my personal, though not statistically large, experience I have come to the conclusion that as a cause for fear among obstetric patients the discovery of the negative Rh factor and its implications is not of such serious import as the disturbing publicity leads patients to anticipate.

SUMMARY AND CONCLUSION

Most causes of fear among obstetric patients are needless or not truly existent. However, some of them are not entirely baseless. These must be discussed frankly and encouragingly with patients, in the light of the scientific medical accomplishments of today.

Obstetricians and gynecologists must understand and practice the humanities as well as the science of the medical profession.

418 Eleventh Street East (1).

VERRUCAE, A DERMATOLOGIC PROBLEM

Chairman's Address

CLINTON W. LANE, M.D.
St. Louis

In dermatology there are many unsolved major and minor problems. In the major group are the collagen diseases, the lymphoblastomas and the disturbances of lipoid metabolism, all of which may affect health life. In the minor group are other dermatoses with a less pronounced effect on the general health but which may be most distressing to the patient, disturbing and baffling to the physician. The wart problem is therapeutic rather than diagnostic, not only because treatment is often ineffectual but because it is difficult to evaluate the results of treatment in lesions reacting as peculiarly and inconsistently as warts.

TYPES OF VERRUCAE

Warts are small, almost universally benign papillary overgrowths, which vary in size, color and shape. They are slightly commoner in women, but certain families seem to have a relatively greater resistance to infection with the wart virus than other families. Warts are autoinoculable and transmissible and may disappear without treatment. There are four distinct types: verruca vulgaris, verruca plana juvenilis, verruca plantaris and verruca acuminata.

Read before the Section on Dermatology and Syphilology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 28, 1950.

Verruca vulgaris, the more commonly observed type, is a raised, circumscribed, solid, round gray or yellowish gray papule varying in size from 2 to 10 mm. The surface at first is flat and smooth but may become scaly, crusted, fissured or cauliflower-like. Warts may be single or multiple; frequently there is a primary "mother wart," which after a variable period of time is joined by other similar satellite lesions. They occur predominantly in children and adolescents and appear most often on the exposed areas, particularly on the hands and fingers, but any portion of the skin surface may be involved. Variants of this type are the threadlike filiform wart of the eyelids and face and the digitate warts which project from the scalp, face and neck.

Verrucae planae juveniles, known as flat warts, are slightly raised, small, flesh-colored, round or angular papular lesions which are distributed over the face, neck, hands and wrists. Almost universally multiple, these lesions occur most often in children and young women. They may be mistaken for vesicles or may closely resemble the papules of lichen planus and, rarely, those of molluscum contagiosum. They produce a "dirty" appearance of the face, when they have coalesced and are located on the chin.

Sites of predilection for verrucae of the plantar type are the padded areas of the soles and heels, less frequently the sides of the feet, the under surfaces of the toes, the palms and palmar surfaces of the fingers. There may be a single wart, but often there are small satellites in the vicinity of the original lesion. Differentiation from a callus and a clavus may be difficult but is facilitated by paring the surface of the verruca. A wart is revealed as a well defined, discrete, gray, round or oval area often containing small dark specks or threadlike lines, which are deposits of blood pigment. The blood has escaped into the basal layer from the dilated vessels of the hypertrophied papillae. If the surface of a callus or corn is pared, a smooth, hard yellow growth containing no blood stains is visualized.

A variant of the plantar wart is the so-called mosaic wart, which has been well described by Montgomery and Montgomery[1]:

> The warty patch is horny and granular with an irregular border and varies in width from 1 to 10 cm Comparatively painless, the patch is located under the pressure points and may extend onto the toes and behind the heels It is often mistaken for callus and may be present for years. Paring reveals the intracellular nature of the patch, which consists of many small individual cores so closely grouped that they resemble a mosaic pattern

Verruca acuminata, known also as condyloma acuminata and venereal wart, occurs chiefly on or about the genitalia and the anus, in the axillas and groins and on the navel. As single or multiple, discrete or confluent, raised, filiform or papillomatous lesions, whose surfaces are often moist and macerated from the secretions of the surrounding organs, they are attached by broad or narrow bases.

ETIOLOGY

Many fantastic theories have been proposed concerning the causation of warts. In the olden days they were often considered as the penalty for indiscretions and sins or as a manifestation of venereal disease. More recently they have been supposedly produced by contact with toads, frogs, lizards and other reptiles and animals. Kühnemann[2] in 1889 claimed that warts were produced by a bacillus, and in 1894 Jadassohn[3] produced warts by subepidermal injections of warty tissue. In 1919 Wile and Kingery[4] reproduced warts by the intracutaneous injection of warty tissue. They postulated that trauma and foreign bodies were portals of entry for an infectious agent, probably a filtrable virus. The incubation period was from four weeks to six months, and in one instance the warts were carried over successfully for two generations. In 1935 Templeton[5] reproduced warts by the intradermal injection of filtrate material and stated that the incubation period may be prolonged from 12 to 20 months. Brain[6] also claimed that it had been established that verrucae were produced by a virus infection. Rulison[7] stated, "The abnormal cellular hypertrophy is due to a local infection with a virus. Whether separate viruses cause the five different forms of verruca or whether the different forms are clinical variations resulting from one virus is unknown." Rudloff[8] believed that venereal vegetations and verruca vulgaris are sister growths due to the same filtrable virus, which manifests itself by papilloma formation on mucous membranes or on thin skin and by wart formation elsewhere.

SYMPTOMS

Verrucae of the vulgaris and flat type seldom produce symptoms severe enough to warrant therapy. Patients present themselves for treatment because they are embarrassed by the appearance and disfigurement of the lesions. This is particularly true if the verrucae are located on the face and hands. The pain and tenderness of plantar warts may be sufficient to seriously hamper the activities of the patient. Verrucae acuminatae may be sensitive, painful and malodorous and may interfere with function.

TREATMENT

The therapy of warts is a difficult problem, and many forms of treatment have been proposed. Wise and Sulzberger stated that "warts are among the most erratic and unpredictable of the dermatoses. Response varies from cases in which a look and a prayer suffice to cases in which lesions persist, recur and even increase despite x-ray, caustics and surgery."

Psychogenic Method.—From the early days of medicine down to the present certain men have believed strongly in the efficacy of the psychogenic method of treatment. In olden times magic was often employed and weird incantations were chanted, often in a graveyard or haunted house. A propitious time for such magic was the waning of the moon. In the modern era the suggestion method was used successfully by

Bonjour,[9] who claimed that all warts are curable by hypnosis. He ascribed cures to the lowering of blood pressure. In 1927 Bloch[10] stated that he had cured 44 per cent of the vulgaris type and 88 per cent of the juvenile type by psychogenic therapy. His method consisted of placing the hands of a blindfolded patient on a vibrating motor, although no current was conducted to the person. The warts were painted with a colored fluid, and after the blindfold was removed the patient was told that the warts would disappear when the color faded. Bloch thought that suggestion provides a stimulus to the vegetative centers, which is conducted by the vegetative nerve channels to the warts. These nervous impulses cause biologic changes of a chemicophysical nature and damage the virus. However, Memmesheimer and Eisenlohr[11] studied 140 cases and found that after six months of observation there were more cures in an untreated group than in those treated by suggestion. There is no satisfactory explanation for the spontaneous disappearance of warts or for the cures produced by suggestion, except that the unstable structure of verrucae makes such results possible.

Peroral and Parenteral Therapy—Peroral medication has many advocates. Drugs reported as producing cures when given orally are mercury compounds, arsenic administered as Fowler's solution (potassium arsenite), arsenic trioxide and acetarsone,[12] dilute hydrochloric acid, thyroid, magnesia, calcium hydroxide solution, arbor vitae, sodium bisulfite, bismuth sodium triglycollamate (bistrimate)[13] and many others. Lurie[14] claimed cures in all of 34 patients who received one to three intramuscular injections of bismuth salicylate. In 1934 Shellow[15] injected potassium bismuth tartrate intramuscularly with good results in only 22.2 per cent of the cases. Sutton[16] endorsed the intravenous injection of neoarsphenamine and sulfarsphenamine, but Allington[17] obtained equally good results from an aqueous yellow solution as from sulfarsphenamine. Other injections reported favorably have been those of autohemotherapy, milk and autolysate material. By the latter method Cormia[18] was successful in 20 per cent of the cases of verruca vulgaris and Biberstein[19] claimed cures in 75 per cent of 139 patients.

Local Therapy.—In 1907 Pusey stated that the only reliable treatment of warts was local destruction. Goldsmith[20] agreed that "Since warts can and often do disappear spontaneously, it is difficult justly to evaluate the efficacy of any treatment that is not directly destructive." Drugs recommended for topical application or superficial puncture are castor oil, potassium hydroxide, acid nitrate of mercury, chromic, nitric and trichloroacetic acids, silver nitrate, phenol, chrysarobin, arsenic paste, Fowler's solution,[21] sulfur, Vleminck's solution and podophyllum.[22] Shellow[15] claimed cures in 91.7 per cent of patients whose warts were injected locally with bismuth potassium tartrate. A 50 per cent solution of urea was beneficial according to Mackay,[23] while Simmons[24] lauded a sclerosing solution. Ethyl chloride, solid carbon dioxide[25] and liquid oxygen[26] have been applied with success, while surgical methods which have been employed effectively are curettage, simple excision, electrolysis, electrodesiccation and actual cautery.

Radiation therapy has many advantages such as ease of application, absence of pain, noninterference with function and avoidance of secondary infection. Therapeutically, roentgen ray and radium are equally efficient, but Osborne and Putnam[27] cited certain advantages of roentgen radiation over radium: 1. Less time is required for treatment; (2) if warts are multiple, large amounts of radium or frequent applications of radium are required, and (3) radium is difficult to apply in some areas and is easy to displace. Most dermatologists prefer and employ roentgen rays, as evidenced by the reports of Hazen and Eichenlaub[28] in 1920, who claimed 93.7 per cent cures, of Michael[29] with 93 per cent cures in 1926 and of Osborne and Putnam,[27] who had 87.7 per cent cures (80 per cent with one treatment and 7.7 per cent with two treatments). The maximum dosage employed by Osborne and Putnam was 8 units, but MacKee[30] advised a maximum dosage of 5 units, with which dosage he had 78 per cent cures in verruca vulgaris and 51 per cent in verruca plantaris. MacKenna[31] gives one dose of 900 to 1,200 r at 100 kilovolts. In a large series of cases of plantar warts Oliver[32] obtained equally excellent results from roentgen and radium irradiation and believed that radiation is the method of choice for this particular type.

PERSONAL EXPERIENCES AND PREFERRED THERAPY

In an experience over a period of 24 years many of the above types of treatment have been employed, some with and many without success. Psychogenic therapy has failed almost universally, probably because the one who employs psychogenic therapy must believe wholeheartedly in its efficacy. In two successful "suggestion cures," which stand out above all others, psychogenic therapy was not intended:

Case 1.—A young man 21 years of age, a student, who had multiple, large verrucae vulgares of the palms was observed in the late hours of a busy day. He requested that no disabling treatment be given because he would have to take examinations the following week. Since there were 30 to 40 warts on each hand a soluble bismuth solution was injected into a solitary wart on each palm. He returned in two weeks presenting smooth palms, completely devoid of warts.

CASE 2.—A surgeon with a verruca vulgaris on the distal phalanx of the right index finger refused radiation therapy and postponed the proposed treatment with actual cautery because of fear of pain and inability to operate for several days. An appointment was made for cautery excision, but prior to the date of the appointment he reported that without any therapy the wart had disappeared. This was either a case of spontaneous cure or one in which fear had produced a disappearance of the lesion.

Verruca Vulgaris.—In the treatment of verruca vulgaris local destruction is the method of choice. For small warts including the filiform and digitate types electrodesiccation with or without local anesthesia is the best treatment. For larger verrucae, either single or few in number, a 1 per cent solution of procaine hydrochloride is injected intradermally and the surface of the wart is seared with the actual cautery. The seared covering is then removed with a curet, revealing a red, soft, gelatinous base, which is destroyed down to firm tissue with the same cautery.

Warts in the beard are prone to recur and spread rapidly because they are frequently traumatized in the process of shaving. They are also removed by electrodesiccation or cautery, but after healing has taken place a 1 or 2 per cent mercurial soap is used to cleanse the face and aureomycin ointment is applied after shaving and before retiring. This has decreased recurrences and has produced cures in recalcitrant cases.

Warts around and beneath the nail are difficult to remove permanently. The method which has afforded the most success consists in trimming the overlying nail to provide complete exposure of the wart and in using a superficial application of monochloroacetic acid followed immediately by a 40 per cent salicylic acid plaster. This is kept in place for one week. When the plaster is removed the soft necrotic tissue is trimmed away with scissors and an antiseptic ointment is applied. At the time of application of the plaster, patients are warned that pain may become severe and that, if so, the plaster should be loosened or removed and compresses of boric acid solution be applied. A single treatment will often provide a cure, but two or three applications may be necessary before the wart yields.

In younger children with multiple verrucae vulgares mercurous iodide is prescribed along with a topical application of 20 per cent salicylic acid, 10 per cent resorcinol and 1 per cent mercury bichloride in 95 per cent alcohol. Twice daily this is applied into each wart with the point of a toothpick. The treatment is often augmented by weekly intramuscular injections of a 1 per cent aqueous solution of mercury bichloride. If such a regimen is unsuccessful, an attempt is made to remove the warts by electrodesiccation, but if multiple injections of procaine or many cauterizations are required, it is recommended that the patient be hospitalized and given a general anesthetic. All warts can then be removed painlessly.

Verruca Plana Juveniles.—Verrucae planae juveniles have been more resistant to treatment than any other type of wart. In this group, which occurs predominantly on the face of children, a successful outcome depends not only on the removal of the wart but on a good cosmetic result. Young persons would seem to be ideal subjects for psychogenic therapy, but in my experience it has almost always failed. The methods which have been of the most benefit are mercurous iodide or arsenic trioxide internally combined with small doses of roentgen radiation (44 to 66 r units) once per week for four weeks. On a few occasions, when some of the verrucae have been treated by means of electrolysis or electrodesiccation not only the treated warts but others on the face have spontaneously disappeared. This may be considered as a form of suggestion therapy. However, despite light desiccation the method may produce undesirable pitted scars. Paulosky and Leider [21] have reported success with the use of Fowler's solution locally. Aureomycin internally or locally may prove helpful in curing this type of wart.

Verruca Acuminata.—The therapy of verruca acuminata has been revolutionized by the discovery of the efficacy of podophyllum for this particular type of wart. In 1944 Culp and Kaplan [22a] reported great success by the application of a 25 per cent solution of podophyllum in mineral oil (liquid petrolatum), and they believed the reaction to be specific. Sullivan [22b] in 1948 found that the component of podophyllum responsible for this success was podophyllotoxin. Sullivan [22c] and other investigators discovered that alcohol was a more suitable vehicle for podophyllum than an oily base, as it can be applied into the crevices of the verruca without spreading to the surrounding areas and it dries more rapidly. These are important attributes, because podophyllum produces a pronounced cytotoxic effect on tissues and such reaction should be limited closely to the lesions requiring treatment. The drug may cause edema, redness, ulceration and pain not only of the wart but of the surrounding tissues. For this reason it should be thoroughly washed from the skin surface within seven or eight hours after its application. Facial lesions should be treated cautiously, because when it comes into contact with the eye podophyllum produces severe conjunctivitis, episcleritis and at times corneal ulceration. Paralleling the excellent results of Culp and Kaplan and of Sullivan all the verrucae acuminatae treated by us have disappeared completely, 80 per cent with one and 20 per cent with two applications. A 20 per cent solution of podophyllum in 95 per cent alcohol is preferred.

Plantar Warts.—Plantar warts are best treated with roentgen radiation, but certain requirements cited by Osborne and Putnam are necessary for effective radiation therapy. These are (1) careful paring of the upper horny surface with a scalpel or razor blade, (2) close approximation of lead foil to the periphery of the wart and (3) immobility of areas under treatment. These measures combined with the routine described by Pipkin, Lehmann and Ressmann [33] are used in our practice. The patient lies flat and comfortably on his abdomen, with leg extended and resting on a fixed, padded, raised, wooden support so that the sole is up and horizontal or nearly so. After the surface of the wart has been pared with a razor blade, the margins of the wart are outlined with ink and an opening is cut in a lead shield to exactly fit this outline. This shield is held in place with adhesive, and a treatment cone with leaded glass tip is applied firmly to the part. The transparent tip gives the operator the advantage of an unobstructed view of the target. One roentgen treatment and one only of 1,500 r (inherent tube filtration 0.5 mm. Al, 85 kv., 5 ma. at a distance of 8 inches [20 cm.]) is administered and the patient is requested to report for observation in six weeks. If the wart has not disappeared an attempt is made to remove the dried base with a dull curet. Should warty tissue still remain, a 40 per cent salicylic acid plaster is applied for four days and this procedure is repeated several times if necessary. If the above treatment is unsuccessful the wart may then be treated with liquid oxygen or solid carbon dioxide. Should all of these methods fail, then cautery or surgical excision is advocated.

---

[33] Pipkin, J. L.; Lehmann, C. F., and Ressmann, A.: Treatment of Plantar Warts by Single Dose Method of Roentgen Ray, South. M. J. **42:** 193-202 (March) 1949.

Although removal of the wart is the objective of treatment, nevertheless the severe after-effects of excessive or repeated radiation must not be overlooked. Too many patients have experienced and are suffering from radiation burns of the feet incurred by improper, careless therapy. Although the dosage of 1,500 r does not remove all plantar verrucae, it does give a satisfactory percentage of cures. Also, it is a safe dosage as to date there have been no severe radiation reactions produced. At the time of the treatment each patient is advised, "You are being given a dosage of roentgen rays which in my experience is capable of removing a majority of warts of this type. If it does not do so your wart is probably not radiosensitive, so never at any time in the future allow anyone to give additional radiation, either roentgen ray or radium, to this particular wart." If this or some similar advice is given fewer patients will be experiencing painful, crippling reactions of the feet and fewer operations for the removal of such inflamed tissue will be required.

The mosaic type of plantar wart is resistant to radiation, and for it the method of Montgomery and Montgomery[34] is recommended. After paring the surface of the wart monochloroacetic acid and a 40 per cent salicylic acid plaster are applied. At weekly intervals the macerated surface is trimmed away and the acid reapplied, provided the previous treatment has not produced severe pain. If intolerable pain occurs, wet compresses and a bland ointment are used until the reaction has subsided. When the wart becomes thinner a strong silver nitrate solution (1 grain to 1 minim) is applied. This routine is continued over a period of weeks or months and produces satisfactory results in a majority of the cases.

For multiple warts of the feet of plantar, mosaic and vulgaris types, particularly when accompanied with excessive perspiration and maceration of the interdigital webs, a satisfactory treatment has been to immerse the soles and sides of the feet in a basin containing a 5 per cent solution of formaldehyde. At first this is done daily, but as the feet become drier the immersions are made less often. During the day a bland powder containing 5 per cent magnesium carbonate and 10 per cent boric acid in talc is applied. This has decreased the perspiration and resultant maceration and has provided a good percentage of cures. It is important to warn the patient to be alert for a possible sensitivity to formaldehyde and to stop the treatment immediately if erythema and burning occur.

SUMMARY

1. The four types of verruca are described briefly.
2. Various types of treatment, reported to have been employed with success, are enumerated.
3. The forms of treatment considered to be the most valuable for each type of verruca are described.
4. Certain precautions are given to protect the patient from undesirable results.

PSYCHIATRY IN 1950

C. CHARLES BURLINGAME, M.D.†
Hartford, Conn.

Where does psychiatry stand today? Its position cannot be stated with any exactitude. As a matter of fact, no one can foretell its future further than to say that it will be permanently a part of medicine. Only in regard to the roads leading to the present can one be specific.

COMPARISON WITH OTHER BRANCHES OF MEDICINE

There is no branch of medicine today more in a state of flux, more talked about and more grossly misunderstood than psychiatry. This is true even among medical men, as witness the senior student body in one important medical teaching center seriously debating the question, "Do you, or do you not, believe in psychiatry?" as if it were a cult. Has anyone in modern times ever heard of medical practitioners debating whether or not they believed in surgery or pediatrics? And then one hears much talk about this, that and the other school of psychiatric thought, each accused of claiming to be right and the others wrong. All of this obscures the sound, sturdy development in psychiatry which has been quietly going on for years.

On other branches of medicine there are many groups of workers, each attacking the unknown, complementing the efforts of the others; each striving for a goal, saying to themselves and to each other, "These things we know; these things we do not know," but never saying, "We believe or we do not believe in some doctrine"; each group working with a certain amount of fact to which they add certain "good hunches" and hypotheses; each group having a wary but healthy respect for all other workers in the field; each group striving for new demonstrable scientific facts which can be integrated with the other demonstrated scientific facts in medicine; each group eventually exposing their findings in the full expectation that their work will be submitted to the grueling test administered by other workers, who, as their scientific duty, will attempt to disprove or to endorse the findings. Such is the true scientific basis of all medical progress in American medicine of today.

---

† Dr. Burlingame died on July 22, 1950. He was president and psychiatrist in chief of the Institute of Living.

Read in the General Scientific Meetings at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 27, 1950.

Because of the emotional storm clouds, the mental thunder and the personality lightning in the field of psychiatry, the members of the medical profession may have the impression that nothing sound and enduring is going on in psychiatry comparable to what is going on in the rest of medicine. Actually, psychiatry is quietly doing a superlative job which merits the confidence and respect of the rest of medicine. The workers in the vineyards of scientific psychiatry have multiplied tremendously in the 40 years and more since I entered the then-rather-desolate field. May I here interpolate that psychiatry is America's prize and oldest example of socialized medicine, which has been the state responsibility for over 100 years. This has been publicized as America's prime medical scandal and example of medical and social lag, in spite of the struggle of conscientious psychiatric leaders.

PSYCHIATRIC PROPAGANDA

Most workers in psychiatry are keenly aware of the unsoundness of the wave of psychiatric propaganda which has swept the country, with its unfortunate reactions. They have been quite aware of the accusations that some psychiatrists have been indiscreet and immodest in their claims. Again, broadcasting such statements as "see a psychiatrist early," "one in 11 persons needs to see a psychiatrist," "one in 20 will spend some time in a mental hospital" (then representing the state hospitals as snake pits) and "one in two hospital beds is psychiatric" has increased the anxiety of a large band of delicately balanced persons. When these remarks are followed with statements that "there are only five or six thousand psychiatrists in the country" and "the average person cannot possibly see one" anxiety is piled on anxiety, with no chance of its being liquidated. In the cancer drive, if the slogan "thump that lump" is popularized, the inability of the patient to see a physician will not make the benign lesion malignant. But one says "thump that lump of anxiety" and because of the shortage of psychiatrists the patient cannot get one to do so. Anxiety has its own malignant tendency to grow upon itself, even though to begin with it may have had no serious import. In short, propaganda, producing an anxiety that cannot be liquidated, creates the very psychiatric condition which it purports to eliminate. These things, however, although they may have been done under a psychiatric banner, should not be charged to psychiatry, the medical specialty.

Psychiatry has become much confused in the public mind with things nonmedical. One finds the papers carrying the story of the psychoanalysis of a motion picture star's pet pup, who was found to be suffering from an acute anxiety neurosis. Again, more recently, the two flyers who had been interned for 18 months in Communist China were interviewed on the radio. The master of ceremonies brought out time and again that, even without freudian training, the boys psychoanalyzed each other and thereby were prepared to analyze their captors and effect their escape. This goes on and on, until the serious-minded medical practitioner, surfeited with this sort of thing, prayerfully mutters, "O death, where is thy sting?" I sometimes think it might be well to substitute the term psychological medicine for the term psychiatry, in order to disidentify this branch of medical practice from the flotsam and jetsam on the psychiatric sea.

DIAGNOSTIC PROBLEMS

In 1950 psychiatry is forced to use diagnostic terms which are merely descriptive of a condition and, with a few exceptions, it has no disease entities corresponding to the diagnosis of pneumonia or appendicitis. Even with this handicap one can treat and prognosticate with improving exactitude. I feel encouraged that, as an etiological and somatic pathologic basis is established, disease entities will be lifted out of the manic-depressive basket, the dementia precox basket and the psychoneurotic basket.

It is known that psychoses and other psychiatric conditions can now be experimentally produced in animals and human volunteers, and the process reversed at will. This at long last parallels what is considered to be a scientific necessity in the study of somatic disease and is reminiscent of Koch's postulate for scientific deduction. These psychotic states can be induced by a variety of methods and agents, such as pituitary adrenocorticotropic (ACTH) and other hormones acting on the adrenocortex, drugs such as diisopropyl fluorophosphate and lysergic acid, and even planned, persistent emotional traumas. Most significant is the fact that these artificial psychoses can be broken up and the syndromes dissipated by some of the present day psychiatric therapies, such as electroshock. Furthermore, these synthetic psychoses can be influenced by psychotherapy, retraining methods and environmental controls. Although no thoughtful man of science will take this single group of facts and consider the battle won, he cannot fail to see the opportunity thus provided to march a whole army of hard-headed scientific workers onto the field.

Today the actual mechanism of mental disease still is not understood, but many investigations of promise are being conducted. Among these is the study of endocrine glands in the production and control of so-called mental disease, i. e., the observed significant alterations in adrenocortical function with the pituitary adrenocorticotropic hormone, sex steroids and other hormones. These are only examples of studies in progress which are closing in on the unknown mechanistic factors of mental disease.

ETIOLOGIC ASPECTS

There is little irrefutable knowledge of the causation of mental disease, but momentarily it is known that there are conditions which are called mental disease. It is known further that these may be produced by bacterial invasions, by dietary dystrophies, by exogenous and endogenous toxins, by physical trauma and fatigue, and also by psychological trauma and emotional strain. On the other hand, the knowledge that physical disease can be produced by emotional causes, which has recently been popularized as psychosomatic medicine, is as old as recorded medical history. Even the term psychosomatic medicine was used over a century ago; then the fashions changed, but now psychosomatic medicine is once more in style. Because of a duality of language, with separate words for mental and bodily processes, physicians came to think of the mind and body as separate, with diseases of the mind and of the body also separate.

There is a psychological side, sometimes minimal, sometimes great, to all so-called somatic ills, whether typhoid with its delirium, gastric ulcer, pneumonia, a malignant lesion or a fracture. And psychiatrists know, or should know, that there is no such thing as a mental disease without some somatic recording. After all, the body is the vehicle of the mind, and it is a scientific impossibility to conceive of the mind and mental disease floating around in a state detached from that vehicle. It would not be flattering to the psychiatrists' powers of deductive reasoning to assume that there is no somatic accompaniment to so-called mental disease just because, with the still imperfect diagnostic methods that are available, it is impossible to identify it. The laboratory observations of today are confirming the thesis that disease is neither mental nor physical but that all disease has different symptomatologic weightings between the psychological and the somatic.

To consider only two types of laboratory investigation, with cytochemistry and the ultraviolet spectromicroscope, psychiatrists are now able to see changes in protein metabolism of the nerve cell as a result of acoustic trauma and fatigue. Can it be that the time is approaching when it will be possible to see positive evidence of mental illness in the nerve cell under the ultraviolet microscope?

The effect of environment on the body, and thus by implication on mental disease, is also being demonstrated. In one experiment Norway rats bred for generations in the effete environment of Baltimore laboratories were found to have only a fraction of the adrenocortex of their wild, "alley-ashcan" distant cousins. When exposed to a new environment, the wild rats with their large adrenals distrusted each other, were overly aggressive, had disturbed behavior patterns and were unable to survive a change in diet. Briefly stated, in rat society they may have been guilty of "psychotic" behavior. In turn, the cultured rats, with their small adrenals, were overly submissive and timid, manifesting their own less vigorous signs of inadaptability. Are the scientific laboratories about to take out of the field of theory and speculation this whole question of the effect of environment on disease and health? Man is an adaptable animal, but just how adaptable?

Impressive indeed is the voluminous literature which each year records the observations and experimentation of laboratory workers. It records studies of changes in behavior, in emotional patterns and in social relationships through the use of surgical operations, chemicals, environment and training. So extensive is it that it would be prohibitive to do more than mention it.

PSYCHOTHERAPY

First among the therapies in 1950 let me mention psychotherapy. In the minds of much of the public and some of the profession, psychotherapy and psychoanalysis have come to mean one and the same thing. This would be analogous to saying that surgery and appendectomy are synonymous. One of the fractions of psychiatry is psychotherapy, and one of the types of psychotherapy is psychoanalysis; within the field of psychoanalysis there are several schools of thought. I believe that psychotherapy, no matter what its form, is essentially personal tutoring, by which I mean understanding guidance in personality development. Today psychotherapy is not an exact science by any means; nevertheless, some form of psychotherapy, even with its imperfections and lack of exactitude, is indispensable.

In the past there has been more heat than enlightenment generated by the vigorous differences of opinion regarding psychotherapy. However, there is beginning to be more enlightenment and less heat with the critical, nonemotional evaluation of results. There has been decided development along the line of simple, practical psychotherapy aiming at positive results in less time and at lower costs. This development, with due consideration for time and money involved and for practicality, has become a prime necessity. The claim that psychotherapy is solely a lucrative way of entertaining suburban ladies is not justified.

But psychotherapy, important as it is, is not the only psychiatric therapy. I am reminded of a little discussed statement of Sigmund Freud in 1920, when, speaking of the endocrine system, he stated, "The structure of psychoanalysis that we have erected is really only a superstructure which at some future time must be placed upon its organic foundation."

Psychotherapy enters into a partnership with rehabilitation. To draw a parallel, the modern surgeon would no longer consider it good surgical care to operate on an elbow and have it heal stiff, useless and in the way. His objective is toward the restoration of function. So it is in psychiatry. The procedure has become extremely practical. Decades ago it was learned that "loafer's delight," either in or out of a hospital, was the greatest foe to mental health and successful psychiatric therapy. Psychiatrists are thinking in terms of restoration, that is, the development of social function, not just keeping the patient busy weaving raffia baskets or rugs, except he be a Navajo Indian for whom that might be a vocation.

Psychiatrists have taken a leaf from the book of modern industry, and now they estimate a person's various capacities, develop and direct his abilities, and, in brief, equip him to go out and do what he must do as a productive member of society. Similar thinking and similar purposeful technics are being used to obviate the necessity for hospitalization. It is no longer considered good psychiatric practice, or good medical practice for that matter, to say "you need a vacation," which once used to be the universal recipe when the medical advisor did not know what else to say. Sardonically enough, however, "loafer's delight" or "do nothing for a while," with its etiological potentialities for mental and physical illness, is gradually receiving great impetus through pension schemes with enforced retirement. These erroneously assume that a man's goal is ultimate idleness. Too often, sudden decompression from carrying heavy responsibility is producing an emotional caisson disease which is gradually appearing in all doctors' offices in all specialties, even though not generally recognized. At least part of the cure is to have the patient reassume real responsibility.

PSYCHOSURGERY

Surgery of the mind is much in the limelight today. The debate about its usefulness should be just about over, with the award last year of the Nobel Prize to Egas Moniz, the originator of psychosurgery. The so-called "ashcan selectivity," which recommended psychosurgery in the long-standing cases in which there was nothing to lose, has moved decidedly in the direction of something more scientific. It is now known that many patients with chronic conditions do not benefit from surgical intervention and that some of those who have more recently become ill may well profit from operation. The temporary blocking out of certain cortical areas of the brain through local anesthesia is one of the many studies, all leading toward a more refined and positive selectivity. Those sophisticated in the procedures have developed a sense of balance extremely necessary in consideration of the sometimes spectacularly good results. Simultaneous with improved selectivity there have been developed several different operative technics from which to choose. All, however, have the objective of producing a new malleability that will permit the restoration of a patient into useful society. With some of the newer technics, it is not uncommon to operate on a patient in the morning and to have him up in the afternoon and in retraining classes the next day. To the question "Will psychosurgery change the personality of this sick person?" the answer is, "I hope so." To the question "Will the patient be made into a vegetable?" the answer is, "to my knowledge no sophisticate in the field has ever seen the operation produce such a metamorphosis." With some of the technics there is not even measurable intellectual impairment. Reeducation after psychosurgery is coming to be regarded as essential in order to break up bad habit patterns, the by-product of mental disease, and to establish socially acceptable habit patterns. To ignore the potentialities of psychosurgery is to be negligent. On the other hand, uncontrolled enthusiasm is frowned upon today.

Shock therapies are now firmly entrenched both in institutional and in office practice. The indications for insulin, pentylenetetrazole (metrazol®), electric shock therapy or their combinations are more specific. No longer does a psychiatrist feel helpless when a depressed or suicidal patient comes to him. He often uses one of the forms of shock therapy to protect the patient from self destruction in the emergency. Simultaneously he moves in with his indispensable psychotherapy or chemotherapy or other psychiatric procedures. The erroneous impression has originated that psychiatrists generally are using the shock therapies to the exclusion of all other forms of treatment. In reality, these are being used in conjunction with all other available forms of therapy. It still is not known how shock therapy works—possibly it is a physiological mechanism, operating through the autonomic or endocrine system. In the shock therapies, also, strides are being made in the matter of selectivity. With the aid of epinephrine and methacholine (mecholyl®) chloride, the time may be approaching when success or failure with shock therapies can be most accurately foretold.

It has long been the dream of psychiatrists to find some drug which would cure mental illness. Such a drug has not been found. The idea of finding any one drug does not appeal to reason. However, the chemotherapists of today are discovering that a number of drugs such as ether administered intravenously, mephenesin, lithium salts, malononitrile and histamine have a definite effect on various phases of mental disorders.

The over-all picture might be summed up by saying that psychiatriy in 1950 embraces psychological, surgical, educational, chemical and physical therapies, all based on a sound knowledge of man's body as well as his mind.

PREVENTIVE PSYCHIATRY

Preventive psychiatry today is more of an aspiration based on multiple theories than a body of fact that can be demonstrated. Be that as it may, I am certain that most preventive psychiatry is, or will come to be, practiced by men in the other branches of medicine. It is those in other branches of medicine who have the opportunity to prevent psychiatric conditions so far as they are preventable. These men know the disease, but must also take time to know the patient. Within reason, they must come to know what the patient's feelings are and why. The following are some simple examples in which there might have been an improvement in the technic.

1. A desiring wife was sent into seventh heaven by being told that at long last she was pregnant. Her medical adviser had known for years how much her whole life was built around having a child. Nevertheless, two months later, with cold, precise, impersonal and scientific exactitude he informed her that hysterectomy was indicated and that she might as well put out of her mind the thought of having a child. The patient did not wait to have her hysterectomy before she had a frank emotional blow-up with suicidal implications.

In this instance, somebody forgot that patients are people.

2. Without having any special grudge against the gynecologists, I recall an instance in which medical students participated in an examination. With the patient on the table, they all examined her and speculated on the diagnostic possibilities, including malignancy, ectopic pregnancy, fibroid and a few other things. Then the woman was given a pat on the back and told to come back in three months to be examined again and to be told whether or not she had a malignant lesion. That was another instance in which an emotional explosion occurred and the psychiatrist was called in during the waiting period.

Here again, someone forgot that patients are people.

3. I wonder how common it is to forget the often devastating psychological effect of advising a woman that she should have a panhysterectomy and that she is not going to have any further use for these organs anyway because she is past the menopause. I wonder whether members of the opposite sex would not also suffer some psychological trauma if something similar were suggested just because their procreative faculties were no longer indispensable.

Women as well as men are people.

4. In the whole broad field of cardiovascular disease there is also the necessity for thinking of patients as people. Everyone knows the futility of frightening a cardiac patient by telling him first that he will have to go slow the rest of his life and that he will have to be prepared to meet his Maker at any time, then telling him to relax and take it easy. Such a prescription, of course, cannot be filled, even by the most phlegmatic.

No disease ever existed without the patient. The disease and the patient are found together. Patients are people. An astonishing job has been done in the technical side of treatment of disease. But the physician must never forget that disease is a mixture of which the personality is always a part.

CONCLUSION

Psychiatry as a part of medicine has experienced a material growth. It is taking cognizance of its responsibilities and is striving to bring its help within the reach of the multitude.

I repeat that in 1950 there is a conscientious, hard-headed, nonvocal psychiatry which deserves the confidence and respect of the public and the profession. It can contribute toward the advancement of the medical sciences, but it also avidly seeks scientific and clinical assistance from all medicine, of which it is a part.

Clinical Notes, Suggestions and New Instruments

ADRENOCORTICOTROPIC HORMONE

Its Successful Use in Keratitis in a Diabetic with Moderate Heart Disease

STEVEN A. MAZAR, M.D.
and
ROBERT M. BOGDASARIAN, M.D.
Binghamton, N. Y.

There have been several reports of the successful use of pituitary adrenocorticotropic hormone (ACTH) in ophthalmologic conditions.[1] We wish to report on its successful use in a case of severe and long-standing superficial disseminated keratitis of the punctate and coalescing type. This had failed to respond to the conventional antibiotic and supportive therapy during a nine month period. After 10 days of therapy with pituitary adrenocorticotropic hormone there was a fairly dramatic improvement that has been sustained for six months. The case is further interesting because the patient is severely diabetic, needing usually 65 units of insulin daily, and because she has severe arteriosclerotic heart disease, compensated only by continued digitalization and by the use of mercurial diuretics once or twice weekly during the past year. Thorn and his associates,[2] in an excellent review of the recent clinical applications of pituitary adrenocorticotropic hormone and cortisone therapy, state, "It appears that the use of ACTH is contraindicated in diabetes mellitus, congestive heart failure, hypertensive cardiovascular disease, Cushing's syndrome, acne, hirsutism, osteoporosis and osteomalacia.

Because of the protracted course and severity of the symptoms of keratitis in this patient and because of her deteriorating morale, she was hospitalized at the Binghamton City Hospital on May 1, 1950. Therapy with pituitary adrenocorticotropic hormone was ventured in spite of the relative difficulties, or perhaps even contraindications, engendered by both the severe diabetic state and the edema-electrolyte disturbances of her heart disease. The potentialities were discussed with the patient and family; the patient was desperate for relief.

REPORT OF A CASE

B. K., a white Jewish woman aged 59, was admitted to the hospital with the chief complaints referable to the right eye: severe pain, scratchy sensations, blurred vision and the entire eye greatly reddened. These had lasted for nine months and had been progressive, with short temporary partial remissions. She had been under the care of several ophthalmologists in succession.

Systemic Review.—Systemic review disclosed the following pertinent history: The patient had not had previous eye troubles; her vision had been good, with the usual refraction changes. She occasionally had left frontal sinusitis. Her hearing was normal. She was edentulous, but wore satisfactory plates. There was no history of unusual repiratory diseases, except for bronchopneumonia, for which she had been hospitalized three times during the period 1944 to 1946. In the past three years she had been hospitalized three additional times for congestive heart failure and twice for severe angina simulating coronary thrombosis. Electrocardiograms never confirmed a true infarction. She had a moderate amount of dyspnea on exertion, orthopnea, a frequent cough and mild peripheral ankle edema. Her cardiac status was fairly well controlled by a low salt diet. She was digitalized most of the time during the past three years, taking 0.2 mg. of digitoxin daily, although she had never been known to have fibrillation; she needed glyceryl trinitrate occasionally for angina. She had needed more and more frequent mercurial injections until half a year ago when she was instructed in self administration of mercaptomerin (thiomerin®) sodium, which she took in 1.0 cc. doses once or twice weekly, her weight and symptoms being her chief guide. In the past her blood pressure tended to be rather high, 160 to 190 systolic and 90 to 100 diastolic.

The patient's appetite was usually good. There was some fatty food intolerance, for which a cholecystectomy was performed in 1924. Ten years ago she weighed 190 pounds (96.2 Kg.). She successfully dieted to around 120 pounds (54.4 Kg.) four years ago, and since then she gradually lost weight to the present range of around 100 pounds (45.4 Kg.). She was habitually constipated and for this she took cascara sagrada pills, one to two every night. She had several drug idiosyncrasies, notably to codeine, and perhaps to morphine and pantopon® (a mixture of opium alkaloids). Whether given orally or parenterally, these caused episodes of severe gastritis.

The diabetes history dated back to 1928. The patient had been variably controlled so far as diet is concerned; strict cooperation from her usually was poor, as she had her own ideas about diet. Not surprisingly, the insulin requirement was gradually increased over the years. From the available records, it was seen that in 1937 she was on a schedule of 25 units of regular insulin (15-0-10); in 1943, 40 units of regular insulin (20-0-20); in 1945, 35 units of protamine zinc insulin and 25 units of regular insulin, given in the morning, and in 1947, 40 units of protamine zinc insulin and 35 of regular insulin. In 1949 she was rather well controlled on 60 units of insulin, 40 protamine zinc insulin and 20 regular insulin. In recent months she was well controlled on 55 units, 35 protamine zinc insulin and 20 regular insulin. Throughout all these years she had few minor insulin reactions and apparently never had been in severe acidosis or coma.

The patient had chronic recurring urinary symptoms dating back to 1919 when, while six months pregnant, cystoscopy was first done for acute urinary retention, apparently due to a stricture. In 1922, a cystotomy was performed for a bladder "stone." In 1941 she had a thorough genitourinary work-up; a meatotomy was done for a urethral stricture, and a urethral caruncle was studied by biopsy and removed by fulguration. She continued to have urinary symptoms for which she had numerous urethral dilations, and several more cystoscopic and pyelographic examinations. However, no gross abnormalities were found. She continued to have a low grade urinary sepsis, manifest by a persistent pyuria with an occasional typical pyelitis attack on the left side. Antibiotics effected temporary ameliorations. She had a myomectomy in 1924 and a hysterectomy in 1926 at the age of 35, with minor and transient menopausal symptoms in their due course.

The patient was an individualist and had her own way in most things, sometimes, unfortunately, even in her medical management. She was despondent at times, expressing thoughts of suicide. Hospital diets were seldom to her liking, and she always insisted on her own selections. However, she was a good worker and managed household duties mostly by herself, a few times unwisely driving herself into cardiac decompensation necessitating hospitalization.

Summary of Past History.—The patient had undergone a cystotomy in 1922, a cholecystectomy in 1924, a myomectomy in 1924 and a hysterectomy in 1926. She had had diabetes mellitus since 1928. A tonsillectomy was performed in 1931. She had had pneumonia three times during the period 1944 to 1946. Numerous cystoscopic examinations had been made since 1919. She had had several acute pyelitis attacks since 1940 and arteriosclerotic heart disease with active symptoms since 1945.

Physical Examination.—The patient was a well developed but poorly nourished woman aged 58, in moderate distress with her right eye. Her left eye was normal. The entire globe and conjunctiva of the right eye were intensely injected; the cornea was opalescent and edematous, and the pupil was widely dilated with atropine. The intraocular tension was within normal limits by palpation. The ears, the nose and the throat were normal except

for a left frontal sinusotomy scar and an edentulous mouth with suitable dentures. Examination of the neck revealed no increased venous distention and no palpable thyroid gland. The chest was emphysematous, and the breasts were normal. The lungs were clear. The heart was not clinically enlarged, there was normal sinus rhythm, the heart sounds were of good quality with accentuation of the aortic second sound, and there were no murmurs. The blood pressure was 155/75 bilaterally. On her abdomen there were three large operative scars. The liver edge was palpable just below the costal margin and tender. Neither spleen nor abdominal masses were palpable. The skin over the abdomen had a peculiar doughy nondependent edema, with a very slow filling of any pitted areas, and the breasts were similarly edematous.

There was edema (1 plus) in the ankles and also minimally in the sacrum, with the same pitting quality mentioned above. Neither cyanosis nor varicose veins were observed. The results of the neurological and rectal examinations were negative.

adrenal glands. We were not prepared to do any 17-ketosteroid urine studies for otherwise demonstrating the effectiveness of our pituitary adrenocorticotropic hormone therapy; hence we continued on clinical grounds alone.

Drug Schedule.—The pituitary adrenocorticotropic hormone was provided in 20 mg. and 10 mg. individual vials with contents dissolved always just prior to the intramuscular injection. Doses were given three times a day at six hour intervals, with night doses omitted. The patient received 60 mg. of the drug in three divided doses on the first day, after which (but coincidental with which, we are sure) anorexia developed; she vomited numerous times for the next few days. Because this disrupted the basal state, difficult at best with the diabetes and the maintenance of cardiac compensation, and because of the patient's anxiety, use of the drug was discontinued and resumed in a week after conditions stabilized again. This time the patient again received 60 mg. of pituitary adrenocorticotropic hormone daily for the first two days (20 mg. three times a day), then 30 mg. of pituitary adrenocorticotropic hormone for the following two days (10 mg. three times a day), then 20 mg. a day for an additional six days (10 mg. twice a day), making a total of 360 mg. On the day following the initial trial of 60 mg., the eye was improved, there was less ciliary injection and the pain was considerably less. The eye continued in its improvement for three days, even while the general clinical picture was deteriorating because of nausea and vomiting and the need for parenteral alimentation. Thereafter, the eye symptoms and findings increased again. When the course of pituitary adrenocorticotropic hormone was resumed, we again noted a significant improvement in the eye within 24 hours; the cornea became clearer, and the ciliary injection decreased. After five days of regular but diminishing amounts of the drug the eye was described as white, though there was minimal ciliary injection at the equators. The cornea was clear, and the patient was pain free.

Course in Hospital.—Preliminary laboratory studies were done for the necessary controls. These are incorporated in the table. A chest roentgenogram revealed normal lung fields and an aortic type heart with a prominent knob. An electrocardiogram revealed normal sinus rhythm, left axis deviation and digitalis effect, all similar to those of her previous graphs. A drop in the total circulating eosinophils is one of the most valuable guides to control of adequate therapy, but this failed when the pretreatment eosinophil count was reported as zero, as were all other eosinophil counts during therapy and one month afterwards. This is an unexplained phenomenon, peculiar to this patient we believe, because concurrent tests were being done regularly on other patients, with the expected average eosinophil counts. An initial white blood cell count was 5,150 with 60 per cent polymorphonuclear leukocytes, 39 per cent lymphocytes and 1 per cent eosinophils. This was from the usual Wright's stain blood smear. This was done at another laboratory. It is interesting that from her 13 previous available hospitalization records over the past 10 years there were never any eosinophils reported, and on two occasions two years apart during supposedly viral pneumonitis, there was leukopenia. The white blood cell count was 3,450, with 60 per cent polymorphonuclear leukocytes, 36 per cent lymphocytes, and 4 per cent mononuclear leukocytes; another count was 3,300, with 63 per cent polymorphonuclears and 37 per cent lymphocytes. We might speculate that the stress of hospitalization and anxiety over the new, expensive and potentially hazardous medicine were effective pretherapy stimuli to our patient's

CLINICAL CONSIDERATIONS

There was considerable euphoria, probably chiefly because of relief from the intractable symptoms of the previous nine months. The patient volunteered that she was ravenously hungry during the course of therapy. She usually experienced a dull headache about half an hour after each of the intramuscular injections. There was a gradual increase in weight from the 93½ pounds (42.43 Kg.) initially to the 102 pounds (43.6 Kg.) on discharge 18 days later, although there was no visible increase in the peculiar edema mentioned above, and perhaps even a decrease. The patient received her mercurial, mercaptomerin (thiomerin®)

sodium, 1.0 cc. every other day, during her hospital stay, whereas her previous requirement at home was twice a week. It was felt desirable to keep her rather dehydrated because of the counterbalancing water retention effect of the pituitary adrenocorticotropic hormone. Some risk is reported to attend this, but the patient was watched for signs of undue fatigue and muscular weakness. Potassium citrate, 15 grains (0.97 Gm.) four times daily, was given one day because of suggestive symptoms. Mecurial diuresis induces a large renal loss of potassium, and Thorn and his co-workers[2] mention it as a contraindication during therapy with pituitary adrenocorticotropic hormone, unless full doses of potassium chloride are being given simultaneously. They mention 1 or 2 Gm. of enteric-coated potassium chloride three times daily.

The initial carbon dioxide-combining power was 41 volumes per cent, and when the determination was repeated just prior to therapy it was 58 volumes per cent. The other two readings were 62 volumes per cent and 60 volumes per cent during pituitary adrenocorticotropic hormone therapy. These are not striking except that in previous hospitalizations, primarily for nondiabetic reasons, the patient's better carbon dioxide-combining powers were usually in the range of 50 to 55 volumes per cent when she was apparently fairly well controlled. The expected physiological effect of pituitary adrenocorticotropic hormone on electrolyte balance is to produce a hypokalemic, hypochloremic alkalosis, and our chemistry studies deviated in that way. The insulin doses given were 10 to 20 units higher once pituitary adrenocorticotropic hormone was started, but the patient was also eating better. It is difficult to say whether this represents a true increased insulin requirement or merely closer and better control. Thorn and his co-workers[2] mention that patients with preexisting diabetes will have their diabetes markedly aggravated by pituitary adrenocorticotropic hormone or cortisone therapy. This was not our experience. All urines were tested for sugar, and a useful means of recording it was designated as a urine sugar profile. For example, on the customary zero to 4 plus basis, if the patient had eight urine specimens in 24 hours, the profile might be read as 31002322. This number shows at a glance the extent of diabetes control as manifest by urine sugar over a 24-hour period. Elkinton and his associates[3] noted in nondiabetic persons a slight glycosuria in three of seven cases on the days when moderate doses of pituitary adrenocorticotropic hormone were given. This glycosuria was associated with slightly increased blood sugar values. The values all reverted to normal when therapy was stopped. Conn, Louis and Johnston[4] noted severe glycosuria after therapy with pituitary adrenocorticotropic hormone, and had convincing evidence that a true diabetic state would develop on long-continued use of the drug in adequate doses. However, Conn and his co-workers also have evidence that the renal threshold for glucose was lowered, making some of this glycosuria renal.

The daily blood pressures varied from 155/75 to 120/70, with the lower levels toward the end of the treatment rather than the other way around. Others have occasionally noted a blood pressure increase during therapy. It may well be that potential hypertension may be brought to light (Sprague[5]).

COMMENT

This represents an initial use of the pituitary adrenocorticotropic hormone by us, and it posed more than the average problems reported in other cases: mainly the severe diabetes, the mercurial-sustained compensation of an arteriosclerotic heart, and the absence of demonstrable eosinophils in the peripheral blood, with consequent loss of a most valuable yardstick by which adrenocortical response is measured. Following the clinical experience of others as far as dosage and methods were concerned and adapting it to our patient, we were able safely to effect a therapeutic response *sine qua non.*

It is well to have a definite plan in mind when initiating a course of pituitary adrenocorticotropic hormone or cortisone therapy, and from our experience in this case and from experiences reviewed in recent literature, the following are effective yet simple guides to therapy control: It is necessary to have conditions stable and basal as nearly as possible, or there will occur too many variables that confuse evaluations. It might be desirable in some cases to begin with saline blank injections for a day or so to test the patient's psychological responsiveness; then unbeknown to the patient and perhaps even the nursing and house staff, the therapy with pituitary adrenocorticotropic hormone should be started, using total circulating eosinophil counts periodically to demonstrate the desired eosinopenia. Lymphopenia, polymorphonuclear leukocytosis, and reticulocytosis are other physiological effects demonstrable by blood cell counts. In our case the total white blood cell count rose slightly but definitely; however, there was no lymphopenia. A daily weight record and an accurate fluid intake and output record will reflect any significant water and salt retention potentials of these drugs. A patient with borderline cardiorenal disease is liable to be pushed into an edema phase quite readily. These data will be a guide to any salt restriction therapy. Daily determinations of urine sugars are easy to do and potentially valuable. Though the reports of steroid diabetes are rare, nevertheless, potential diabetes might well be brought to light, as suggested by Thorn.[2a] An initial fasting blood sugar determination is desirable as a base line for any future repeat blood sugar determinations. Blood pressure determinations once or twice daily are similarly potentially valuable, although here again, though a true hypertension may not be really created, an existing hypertension may be aggravated. Electrolyte studies are desirable during the therapy when signs or symptoms are suggestive, for example, the muscle weakness of hypopotassemia or the asthenia of adrenocortical exhaustion from overstimulation with pituitary adrenocorticotropic hormone. It is undesirable to stop a course of therapy abruptly, and the present trend is to taper off gradually with diminishing doses to prevent a sudden collapse of adrenocortical function. It is necessary to bear in mind the adverse effects of the drugs on healing of wounds; Ragan and his co-workers[6] first noted this when biopsy wounds in patients with rheumatoid arthritis treated with cortisone were slow to heal.

Pituitary adrenocorticotropic hormone and cortisone have such a vast therapeutic spectrum that it is well to observe all the benefits or ill effects that the patient derives, subjectively and objectively, and not just those pertinent to the initial reasons for the therapy. Sprague and his associates[5] present a very comprehensive review of their observations on the physiological effects of cortisone and pituitary adrenocorticotropic hormone in man. Many of these physiological effects may bear evaluation in each patient, development or increase of acne, hirsutism, moon facies and delayed menses in women. Gout can be precipitated by therapy with pituitary adrenocorticotropic hormone, as well as treated by it. Myasthenia gravis can initially be seriously worsened by the therapy, before any subsequent benefit is noted.[7] Euphoria or mental depression may develop, especially after prolonged therapy.

SUMMARY

A case of severe keratitis of nine months' duration, unresponsive to the usual therapies, was promptly and successfully treated with pituitary adrenocorticotropic hormone (ACTH) in a total dosage of 360 mg., over a 10-day treatment period.

The treatment was complicated by the fact that the patient was severely diabetic, requiring 65 units of insulin daily, and had moderately severe cardiac disease, requiring biweekly mercurials for compensation.

The diabetes was not particularly aggravated, nor was the state of compensation too difficult to maintain.

The patient has not had a relapse after six months of a clinical cure of the keratitis.

THERAPEUTIC EFFECT OF PITUITARY ADRENOCORTICOTROPIC HORMONE (ACTH) IN A CASE OF HENOCH-SCHONLEIN VASCULAR (ANAPHYLACTOID) PURPURA

MARIO STEFANINI, M.D.
CHARLES A. ROY, M.D.
LEDA ZANNOS, M.D.
and
WILLIAM DAMESHEK, M.D.
Boston

Increasing attention has recently been focused on a group of conditions characterized by a widespread alteration of the collagenous tissue. Active vasculitis of various regions appears to be, among other characteristics, a fairly constant common denominator in this group of diseases which includes such heterogeneous conditions as disseminated lupus erythematosus, acute glomerulonephritis, polyarteritis nodosa and serum sickness. Some of these conditions have a possible allergic causation, while in others the pathogenetic mechanism is obscure. Recently an additional characteristic has come to the fore, i. e., a variably favorable response to treatment with anterior pituitary adrenocorticotropic hormone (ACTH).[1]

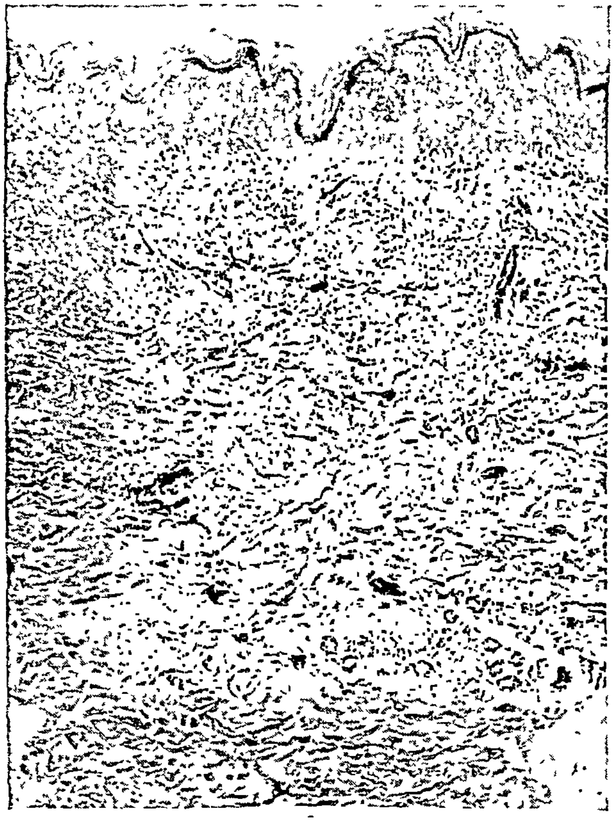

Fig. 1.—Microscopic appearance of a section of skin before pituitary adrenocorticotropic hormone therapy. Active inflammatory reaction centered around the small vessels and capillaries, which appear destroyed in some areas (× 110).

The nonthrombopenic Henoch-Schonlein type of vascular or anaphylactoid purpura is another condition which may be related to this group in view of its possible allergic basis and its severe generalized vasculitis. The classic capillary lesions are represented by active inflammatory changes centered around the smallest vessels with infiltration of inflammatory cells, and destruction and dilatation of capillaries. Edema of the epidermis and corium may also be present in the affected areas.

Because of these considerations we thought it of interest to observe the effects of treatment with pituitary adrenocorticotropic hormone in a case of severe vascular anaphylactoid purpura of the nonthrombopenic type, with associated glomerular involvement.

REPORT OF CASE

D. F., a boy aged 3 years, was admitted to the Boston Floating Hospital on Feb. 24, 1950. The family and past history were noncontributory. During the last week of January 1950 the patient had on his face a few red pin-point spots which disappeared in a few hours. At the same time, he experienced pain and difficulty in walking and his parents noticed moderate swelling and tenderness of both his ankles for a day or two. On Feb 6, 1950 many purpuric lesions were noticed on the extremities and buttocks. On his admission to another hospital the following observations were recorded: The temperature was 100 F. rectally; purpuric dark red spots, not disappearing with pressure, were seen over extremities, face, hypogastrium and genitalia; the tonsils were moderately enlarged and infected, there was acute otitis media of the right side, and the ankles were moderately swollen. A diagnosis of meningococcemia was considered, and sulfadiazine was given for five days, when it was discontinued because of gastric intolerance and the appearance of acetylsulfadiazine crystals in the urine. Laboratory examinations revealed a Streptococcus viridans in the throat culture; blood cultures were negative for Meningococcus, Typhus and Brucella. The bone marrow and peripheral blood appeared normal. Clotting, bleeding and prothrombin times were also within normal limits. Occult blood was found in the stools and vomitus.

On February 20, while the previous skin lesions were fading away, a new hemorrhagic rash appeared, large and confluent, involving all the extremities. Edema of the face, headache and cramplike abdominal pain at irregular intervals presented themselves at the same time. On February 23 about 1 teaspoon of red blood was passed with a bowel movement. The patient was then referred to the Boston Floating Hospital for further study. On examination the child complained of intermittent severe abdominal pain. He appeared rather pale. The skin over the extremities, buttocks and face was covered with purpuric spots varying in size and shape and mostly located on the extensor surfaces. Some of the lesions were elevated and some were excoriated as the result of scratching. Other positive observations included a grade 2 systolic murmur heard best in the third and fourth left intercostal space and transmitted over the entire precordium, the liver edge palpable 1 fingerbreadth below the costal margin and moderate swelling of the left ankle. The abdomen was tender without rigidity. Swab culture of the throat again revealed Strep. viridans and a nonhemolytic Streptococcus. Blood examination disclosed a moderate grade of anemia (red blood cells 3,120,000; hemoglobin 60 per cent) and normal leukocytes: there were 7,500 white blood cells, with a differential count of polymorphonuclear leukocytes 45 per cent, lymphocytes 37 per cent, monocytes 15 per cent, basophils 1 per cent and eosinophils 2 per cent; there was a normal platelet level and a normal bone marrow. The sedimentation rate (Westergren) was 11 mm. in one hour. Examination of the urine revealed faint traces of albumin, and the sediment showed 15 red blood cells and four white blood cells per high power field.

Tests for study of the hemostatic mechanism gave the following results: platelets, 380,000 per cubic millimeter; bleeding time, 3½ minutes; tourniquet test, negative; clotting time, 5 minutes; prothrombin activity, 100 per cent; labile factor activity, 100 per cent; clot retraction, normal; prothrombin activity of serum, 8 per cent (one hour after completion of coagulation), and serum/plasma prothrombin activity ratio, 8 0. No fibrinolysis was evident after 48 hours of incubation of the clot at 37 C. There was no demonstrable anticoagulant. In the tourniquet test 22 petechiae appeared in an area 1 inch in diameter after application of infradiastolic pressure for 10 minutes.

This work was supported in part by grants from the C. H. Hood Dairy Foundation and the American Cancer Society, Massachusetts Division.

This work was completed during the tenure of a Damon Runyon Clinical Research Fellowship (Dr. Stefanini) administered by the American Cancer Society.

From the Ziskind Laboratories (Hematology Section) of the Joseph H. Pratt and New England Center Hospitals, the Boston Floating Hospital and the Departments of Medicine and Pediatrics, Tufts College Medical School.

Dr. James Marvin Baty, professor of pediatrics, Tufts College Medical School, and physician in chief, Boston Floating Hospital, enabled us to study this case. Dr. H. Edward Mac Mahon, professor of pathology and bacteriology, Tufts College Medical School, interpreted the microscopic sections.

[1] Thorn, G. W., and others: Medical Progress: The Clinical Usefulness of ACTH and Cortisone, New England J. Med. **242**:783-793 (May) 1950.

Occult blood was detected in the stools. The nonprotein nitrogen level of the blood was 22 mg. per 100 cc. Roentgenograms of the long bones and chest showed no abnormalities. Lumbar puncture revealed clear fluid under normal pressure; the total protein was 9.2 mg., sugar 84 mg. and chlorides 708 mg., per 100 cc., and a culture was negative.

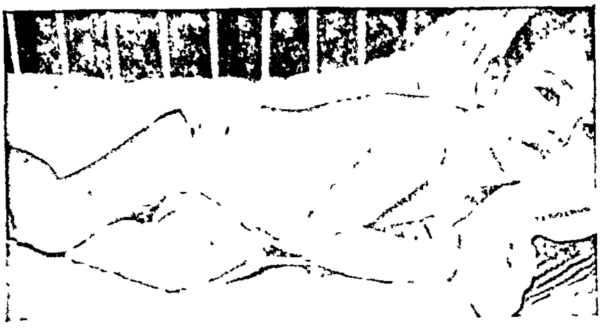

Fig. 2—Photograph of the patient at the beginning of pituitary adrenocorticotropic hormone therapy.

The patient was kept under observation and given penicillin, 300,000 Oxford units a day. The purpuric rash slowly cleared; by the sixteenth hospital day it had almost completely disappeared The stools were still positive for blood, and the child had intermittent severe abdominal pains Daily urinalysis continued to show moderate albuminuria, presence of red and white blood cells in the sediment and, at times, coarse granular casts.

On the fifteenth hospital day the petecchial rash reappeared with the same intensity as on admission The patient was then given aureomycin hydrochloride, 100 mg. every four hours. After six days of such treatment without improvement of the child, whose abdominal pains became more frequent and severe, pituitary adrenocorticotropic hormone therapy was started in a dosage of 5 mg. given three times a day subcutaneously. This preparation was supplied by Dr. E. B. Astwood and is a glacial acetic acid extract derived from pork pituitary gland.[2] At this time a skin biopsy was made. The specimen consisted of an elliptical piece of skin with a subcutaneous depth of 0.6 cm. The most striking change was the exceedingly active inflammatory reaction centered about the small vessels or capillaries, especially in the superficial layer of the corium. Capillaries were destroyed in some areas, dilated in others. This type of inflammatory reaction accompanied by hemorrhage is consistent with Henoch-Schönlein purpura but may also appear in other peripheral vascular diseases showing acute reactive inflammatory changes (fig. 1). The appearance of the skin of the patient at the beginning of hormone therapy is indicated in figure 2.

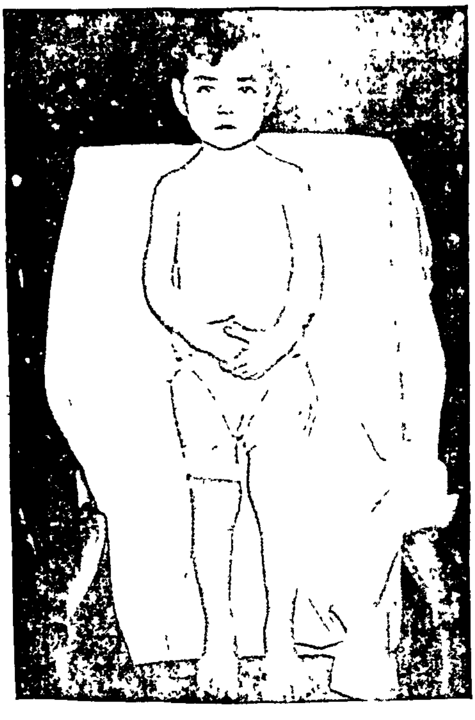

Fig 3—Photograph of the patient at the suspension of therapy. Note the residual pigmentation in areas that previously had hemorrhagic lesions. Only a few new petecchiae are present

Treatment with pituitary adrenocorticotropic hormone was continued for fourteen days, and a total of 210 mg was administered together with a low salt diet. A total gain in weight of 3 pounds (1.3 Kg.) was noticed, but the blood pressure remained within normal limits throughout the entire course of therapy. The cutaneous lesions improved rapidly and almost completely disappeared after six days of treatment (fig. 3). Abdominal pains subsided early during therapy. The urine also became more nearly normal, as the albuminuria diminished and casts were no longer observed in the sediment. The personality of the child was strikingly affected; although on admission he had appeared shy and withdrawn, he later became active and even aggressive. At the time of suspension of therapy a second skin biopsy taken in the only area of fresh hemorrhage showed massive hemorrhage into the corium and underlying tissue. The epidermis was intact. The active inflammatory disturbance previously noted had almost completely disappeared, and the reticular layer of the corium now showed the most minimal perivascular lymphocytic infiltration. The skin appendages were not affected (fig. 4).

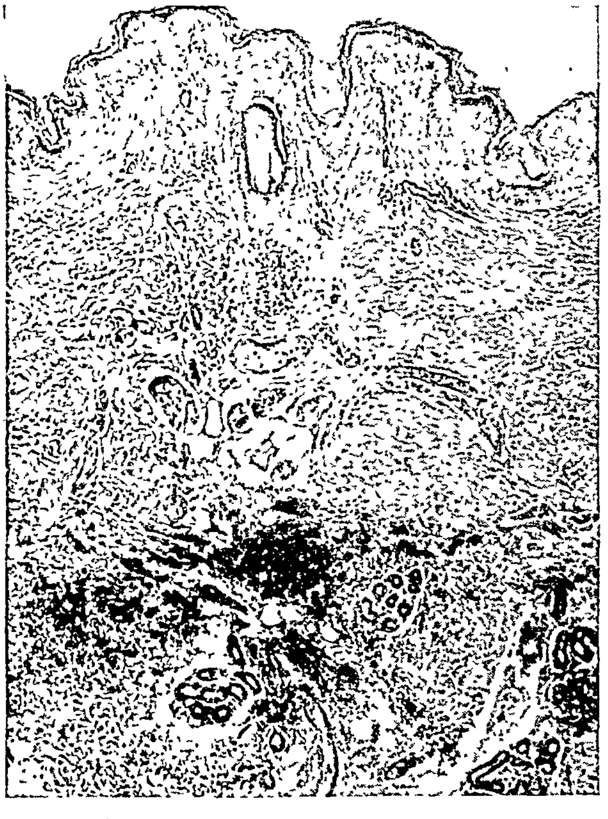

Fig 4—Microscopic appearance of a section of skin taken immediately after suspension of pituitary adrenocorticotropic hormone therapy. The section was taken in an area of fresh hemorrhage; hence, most of the infiltrating cells are erythrocytes and the perivascular lymphocytic infiltration is minimal (× 110).

Six days after pituitary adrenocorticotropic hormone therapy was discontinued new small purpuric lesions reappeared on the lower extremities and mild abdominal pains also recurred. Both symptoms receded promptly, and one month after discontinuing hormone therapy (April 19, 1950) the patient was discharged asymptomatic. The urine, however, again showed 0.5

[2] Astwood, E B; Cleroux, A. P.; Payne, R. W, and Raben, M. A.: Therapeutic Studies on Some Newer Corticotrophic (ACTH) preparations, Bull New England M. Center **12:** 2-10 (Feb) 1950.

per cent of albumin and a few granular casts in the sediment besides red cells and white cells, which had never disappeared altogether even during therapy.

After his return home the patient felt well, gained some weight and played actively. He was readmitted one month later (May 15, 1950). Sixteen hours before admission, he had felt feverish and complained of headache and weakness in his legs. The next morning he had passed port-wine-colored and smoky urine. At examination the temperature was 103.4 F. and the blood pressure 100/60. A few purpuric spots were noted on both cheeks. Laboratory examinations showed reddish urine that contained albumin (0.5 per cent); red blood cells (80 per field) and white blood cells (4 per field), and a few fine granular casts. The nonprotein nitrogen level was 48 mg. per 100 cc. Blood examination revealed a mild hypochromic anemia. Penicillin 50,000 units every four hours was given, and the temperature quickly fell to normal. Four days after admission a few purpuric spots were noted on the ankles, legs and elbows. They faded the following day. At no time did the patient complain of abdominal pain, nor was occult blood detected in the stools during this admission. Throat culture again revealed Streptococcus viridans.

Effect of Pituitary Adrenocorticotropic Hormone (ACTH) Therapy on the Urinary Findings in a Case of Anaphylactoid Purpura with Glomerular Involvement

Days After Start of Therapy *	R. B. C. Per Field	W. B. C. Per Field	Albumin Percentage	Casts † Per Field
0	16	12	0.5	1.2
5	16	10	0.2	3.0
11	40	15	0.2	0
15	15	14	0.05	0
30	18	5	0.5	0.5
45	15	9	0.5	0
75	60	4	0.5	0.4
120	20	8	0.3	0.6

* Therapy was suspended on the fifteenth day.
† Casts were mostly fine, of the granular and epithelial type.

Phenolsulfonphthalein elimination was normal; intravenous pyelography failed to show any abnormality. The serum protein level was 6.5 Gm. per 100 cc. (albumin 3.6 Gm. and globulin 2.6 Gm.).

Since then, the patient has remained in good condition. The urine appears normal in color and specific gravity, but a small amount of albumin is still present, as are red and white blood cells and a few casts in the sediment. At the time of writing (four months after the cessation of therapy) the patient enjoys perfect health, but the urinary findings are still unchanged. A nonprotein nitrogen determination gives a value of 31 mg. per 100 cc.

COMMENT

The diagnosis of Henoch-Schönlein nonthrombopenic purpura in this case seems to be fairly certain, in the light of the following rather characteristic clinical and laboratory observations: (*a*) the sudden occurrence and frequent recurrence of purpuric manifestations; (*b*) the association of the purpura with melena and hematuria, indicating the involvement by the vasculitic process of intestinal tract and kidney; (*c*) the articular symptoms early in the course of the condition, and (*d*) the laboratory results, showing increased capillary fragility but a normal mechanism of blood coagulation and normal bleeding time in a subject with purpura.

Several therapeutic agents have been suggested from time to time for the treatment of anaphylactoid purpura. Citrin (vitamin P, hesperidin), ascorbic acid, rutin and antihistamine drugs have been recommended and have given good, and sometimes spectacular, results in individual cases. The evaluation of any therapeutic procedure in this disease is difficult, however, because the disease presents frequent spontaneous remissions.

The same limitation applies to the evaluation of pituitary adrenocorticotropic hormone therapy in our case. As often happens with this disease, antibiotic therapy failed to modify the condition. On the other hand, treatment with the hormone agent undoubtedly influenced the process at least to some extent. The disappearance of abdominal symptoms was prompt and striking, and the skin lesions faded early during therapy. Skin biopsies taken in two areas of fresh hemorrhage at the beginning and at the end of therapy indicated a striking regression of the vasculitic changes. However, the hormone did not eradicate the disease. Small numbers of petechiae appeared even during therapy; purpuric spots and abdominal symptoms recurred temporarily after the suspension of treatment. The renal manifestations of the disease were only temporarily improved (see the accompanying table), and the establishment of a chronic nephritic process, a common occurrence in anaphylactoid purpura, was not prevented by pituitary adrenocorticotropic hormone therapy.

Particularly remarkable was the change in personality of the patient, who was shy and introverted before his disease and at the time of admission but became extroverted and aggressive shortly after the suspension of hormone therapy. After his discharge from the hospital the patient soon reverted to his withdrawn attitude.

SUMMARY

A case of severe anaphylactoid purpura of the nonthrombopenic Henoch-Schönlein-type with glomerular involvement in a child 3 years of age was treated with pituitary adrenocorticotropic hormone (ACTH), with the following results:

(*a*) The treatment was followed by striking regression of the vasculitic changes characteristic of the disease. The abdominal symptoms were promptly relieved and the cutaneous hemorrhagic manifestations diminished quickly.

(*b*) Mild abdominal symptoms and petechial manifestations reappeared after the suspension of the therapy but regressed spontaneously in a short time.

(*c*) The signs of renal involvement were only temporarily affected by hormone therapy, which did not prevent the establishment of a mild chronic glomerulonephritis.

(*d*) Remarkable changes in the personality of the patient were observed; these regressed shortly after the suspension of therapy.

Council on Foods and Nutrition

ACCEPTED FOODS

The following products have been accepted as conforming to the rules of the Council.

JAMES R. WILSON, M.D., *Secretary.*

Clapp's Baby Food Division, American Home Foods, Inc., Rochester, N. Y.

CLAPP'S STRAINED SWEET POTATOES. Ingredients: Sweet potatoes, malt syrup, salt and water necessary for preparation.

Analysis (submitted by manufacturer).—Total solids 15.97%, moisture 84.03%, ash 0.99%, fat (ether extract) 0.04%, protein (N × 6.25) 0.93%, crude fiber 0.51%, carbohydrates other than crude fiber (by difference) 13.82%.

Vitamins and Minerals	Mg./100 Gm.
Carotene	2.03
Thiamine	0.024
Riboflavin	0.072
Ascorbic acid	2.55
Nicotinic acid	0.385
Calcium	14.80
Phosphorus	40.20
Iron	0.72
Copper	0.38

Calories.—0.57 per gram; 16.28 per ounce.

Use.—For use in the feeding of infants, convalescents and others requiring a soft diet.

The Gerber Products Company, Fremont, Mich.

GERBER'S READY TO SERVE RICE CEREAL. Ingredients: rice flour, invert sugar syrup, dicalcium phosphate, rice bran oil, salt, water extract of rice bran, sodium iron pyrophosphate, nicotinamide, thiamine hydrochloride, and riboflavin.

Analysis (submitted by manufacturer).—Total solids 95.2%, moisture 4.8%, ash (minerals) 3.9%, fat (acid hydrolysis) 5.5%, protein (N × 6.25) 5.1%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 80.4%.

Vitamins and Minerals	Mg./100 Gm.
Thiamine	6.88
Riboflavin	0.88
Nicotinic acid	6.9
Calcium	605
Phosphorus	680
Iron	70

Calories.—3.90 per gram; 111 per ounce.

Use.—For use in the feeding of infants and young children.

Council on Physical Medicine and Rehabilitation

REPORT OF THE COUNCIL

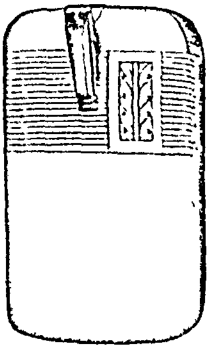
The Council on Physical Medicine and Rehabilitation has authorized publication of the following reports.

HOWARD A. CARTER, *Secretary.*

SILVERTONE HEARING AID, MODEL P-15, ACCEPTED

Manufacturer: W. E. Johnston Manufacturing Company, 708 West 40th Street, Minneapolis.

Distributor: Sears, Roebuck & Company, 925 South Homan Avenue, Chicago 7.

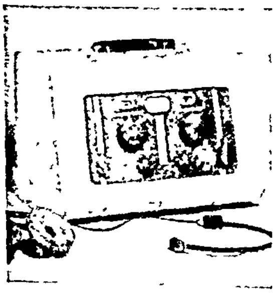


Silvertone Hearing Aid Model P-15

The Silvertone Hearing Aid, Model P-15, is an electric device recommended for the rehabilitation of the hard-of-hearing. Without the clothing clips, the case measures 85 by 58 by 21 mm. The weight of the instrument without batteries is 83 Gm. Receiver and cord weigh 11.5 Gm. and batteries 47.5 Gm., so that the total weight is 142 Gm. The Council's investigation showed that the instrument performed as represented by the manufacturer and that it met the requirements for acceptance. The Council on Physical Medicine and Rehabilitation voted to include the Silvertone Hearing Aid, Model P-15, in its list of accepted devices.

MICROTONE ADC AUDIOMETER, MODEL 53-C1, ACCEPTED

Manufacturer: The Microtone Company, Ford Parkway on the Mississippi, St. Paul 1.



Microtone ADC Portable Audiometer, Model 53-C1

The Microtone ADC Audiometer, Model 53-C1, is a portable instrument for testing a patient's hearing. It requires a source of 100 to 130 volt alternating current, being equipped to compensate for variations of line-voltage within this range. It is a pure tone audiometer and is equipped with both bone conduction and air conduction receivers. There is a microphone for communication with the patient during tests. Evidence obtained from a source acceptable to the Council indicated that this apparatus satisfies the Council's minimum requirements for the acceptance of audiometers. The Council on Physical Medicine and Rehabilitation voted to include the Microtone ADC Audiometer, Model 53-C1, in its list of accepted devices.

NATIONAL HEARING AID, ULTRATHIN MODEL 504, ACCEPTED

Manufacturer: National Hearing Aid Laboratories, 815 South Hill Street, Los Angeles 14.

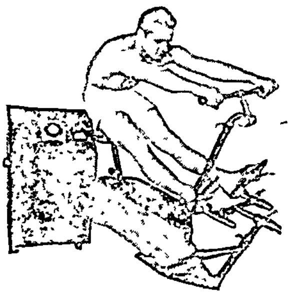
The National Hearing Aid, Ultrathin Model 504, is an electric device recommended for the rehabilitation of the hard-of-hearing. With the exclusion of the clothing clips at the side, the case measures 114 by 60 by 24 mm. (tapering to 20 mm.), and the transmitter unit, without batteries, receiver cord and receiver, weighs 110.5 Gm. With batteries, receiver cord and receiver, the hearing aid weighs 170.5 Gm. It requires the usual zinc-carbon A and B batteries.

The Council's test of the instrument showed that it met the requirements for acceptance and that the performance, construction and material were as represented by the firm. The Council on Physical Medicine and Rehabilitation voted to include the National Hearing Aid, Ultrathin Model 504, in its list of accepted devices.

BROCKMAN THERAPEUTIC EXERCISER ACCEPTED

Manufacturer: Brockman Manufacturing Company, 25 Rockhill Road, Bala-Cynwyd, Pa.

The Brockman Therapeutic Exerciser is designed for giving active and passive exercise to patients. It resembles a bicycle in having a seat, handle bars and pedals. The rate of pedaling is governed by an electronic control housed in a cabinet, and the power is furnished by a motor which requires a source of 60-cycle alternating current at 110 volts and consumes 330 watts of power. The leather-covered adjustable seat is stationary, providing security for the patient. There are graduation marks for the seat level adjustment, the handle adjustments and the pedal arms. The reach to the handles provides variations for adapting the exerciser to both children and adults. After the initial adjustments these readings can be recorded on the patient's chart and the apparatus set for each individual patient.



Brockman Therapeutic Exerciser.

When the apparatus is used for active exercise, increments of resistance may be added by means of an electronic control. When it is used for passive exercise, the speed may be varied from slow to brisk activity; the movements of the pedals can also be reversed The ankle can be placed either in front of or behind the axis of the pedal, so that the work can be distributed among the flexors and extensors of the ankle at will. Most patients find that they can get on and off the apparatus without aid.

Essential Measurements

* For domestic shipment only.

As with any power-driven apparatus, the patients must be selected carefully. Without power the machine is not free-moving but requires more than minimal effort to start and maintain motion. Assistance to the pedal motion is possible by applying pressure on the handles, which are mechanically coupled to the pedals. The apparatus must be used with caution. This exerciser does not replace the foot-driven bicycles already in use. It is useful in rehabilitation of various parts of the body, including the arms, shoulders, back and lower extremities.

The Council on Physical Medicine and Rehabilitation voted to include the Brockman Therapeutic Exerciser in its list of accepted devices.

SATURDAY, DECEMBER 16, 1950

THE CLEVELAND MEETING OF THE AMERICAN MEDICAL ASSOCIATION

The recent Clinical Session of the American Medical Association at Cleveland fulfilled once again the desires of those in attendance who were looking for up-to-date scientific information particularly intended for the general practitioner. It also indicated an increasing alertness on the part of the medical profession to its responsibilities in civic and other affairs that concern the health of the people of this nation.

Several thousand visitors, including physicians, medical students, nurses, exhibitors at the technical exhibits and guests, attended the meeting places for the Association's activities. The demonstrations and lectures sponsored in the Scientific Exhibit and lecture halls, the color telecast of surgical procedures and demonstrations, the medical motion pictures, the quality of the Technical Exhibit and the actions of the House of Delegates reflected clearly the breadth of activities and the interest of the participants at a Clinical Session of the American Medical Association.

SCIENTIFIC ACTIVITIES

The scientific sessions were planned to summarize current information on medical advances in various fields. Included in the general topics were discussions of cancer, heart and blood vessel diseases, diabetes, diseases of children, surgery, anesthesia and poliomyelitis. More than 80 prominent physicians participated in the lectures or demonstrations. Supplementing the lectures and demonstrations were 70 exhibits essentially devoted to the subjects mentioned. Even practical laboratory demonstrations were found as a prominent part of the scientific exhibits.

THE TECHNICAL EXHIBITS

More than 145 firms participated in the technical exhibits. Manufacturers of apparatus, dietary products and drugs and publishers were among those who were represented in this informative and interesting feature. During the past years there has been an obvious trend toward the development of more scientific presentations in the technical exhibits, and the commendations offered by passing physicians indicate the value of this trend.

HOUSE OF DELEGATES

The House of Delegates had a record attendance. Of 198 eligible delegates, 195 were seated on the opening day. They represent the constituent state and territorial associations, the Scientific Sections of the American Medical Association and the medical departments of the armed forces, the United States Public Health Service and the Veterans Administration. The large registration of delegates and their continued attendance revealed their serious interest in medical affairs. Perhaps most significant of the closeness of their interest is the fact that not one of the reports offered to the House by the Reference Committees was changed. As the Speaker of the House, Dr. F. F. Borzell of Philadelphia, pointed out, this surely indicated that the meetings of the Reference Committees had been well attended, the subjects thoroughly discussed and the delegates satisfied that the committees reported out the consensus of those in attendance.

The proceedings of the House of Delegates will be reported in THE JOURNAL beginning with the December 23 issue. Each action of the House will be given in sufficient detail to permit the reader to learn the reports of the reference committees and the disposition of these reports by the House. The complete proceedings will be made available as usual in a bound volume that will be sent to all officers of the Association and to all members of the House of Delegates. Others who may want a copy should communicate with Dr. George F. Lull, Secretary of the Association.

One of the earliest actions of the House was to choose the General Practitioner of the year, Dean Sherwood Luce of Massachusetts. Each county medical society is permitted to propose a candidate for this award. From these nominees one is selected from each state. The state list then is studied by the Board of Trustees, which presents three names to the House of Delegates, which by ballot selects the recipient.

The address of the President of the American Medical Association was published in the December 9 issue of THE JOURNAL. In the same issue appeared a statement from Mr. William L. Hutcheson, General President, United Brotherhood of Carpenters and Joiners of America, which was read before the joint meeting of the House of Delegates and the National Education Campaign. Because of illness Mr. Hutcheson could not appear, and his address was read by Peter E. Terzick, editor of *The Carpenter*. These addresses and others of great interest and significance will be made available for the members of the profession through other mediums. Also available will be the addresses presented at the third annual Medical Public Relations Conference, which was held immediately preceding the meetings of the American Medical Association and which was attended by more than 300 persons interested in public relations.

SECTION ON MILITARY MEDICINE

The House of Delegates, following a recommendation from the Council on Scientific Assembly, established a new Section on Military Medicine.

MEMBERSHIP

In an early issue of The Journal will be another series of questions and answers relating to membership and fellowship in the American Medical Association. These will appear in the Organization Section of The Journal. In the meantime, because of the many questions that have been raised concerning them, a summary of some actions considered by the House of Delegates is reported here. The House decided that fellowship and membership dues should be continued. Annual dues for members will include subscription to The Journal of the American Medical Association, an action taken by the House of Delegates at the 1950 Annual Session. An active member will be considered delinquent if his dues are not paid by December 31 of the year for which dues are prescribed and shall forfeit his active membership in the American Medical Association if he fails to pay the delinquent dues within 30 days after the notice of his delinquency has been mailed by the Secretary of the American Medical Association to his last known address. The Board of Trustees may excuse a member from paying dues when it is deemed advisable, provided that the member is excused from payment of his full dues by his component society and constituent association. However, all physicians who are engaged in the active practice of medicine, regardless of whether they are excused from payment of dues by a state association, must pay dues to the American Medical Association unless such payment would be a hardship. A physician who pays only partial dues to his county and state societies owing to hardship will be exempted from payment of A. M. A. dues but will not receive The Journal. This exemption will not be granted, however, except on written recommendation of the secretary of the county or state society in which the physician resides.

COMMITTEE ON CONSTITUTION AND BY-LAWS

An Interim Committee on Constitution and By-Laws reported several recommendations to the House of Delegates. At the conclusion of the report the House adopted action whereby this committee will continue until the 1951 annual session of the House, at which time a permanent committee on the Constitution and By-Laws will be activated. The new standing committee will consist of five member or service fellows elected by the House of Delegates on nomination by the Board of Trustees for terms of five years, so arranged that at each annual session the term of one member expires. The President, Secretary, Assistant Secretary, a member of the Board of Trustees and the Speaker and Vice Speaker of the House of Delegates will be ex officio members without the right to vote. The Committee will be fact finding and advisory and will report to the House of Delegates.

COMING A. M. A. MEETINGS

Among the items of general interest to the readers of The Journal is the supplementary report of the Council on Scientific Assembly which recorded the appointment by the Board of Trustees of Dr. James T. Billups of Houston, Texas, as Chairman of the Local Committee on Arrangements for the Houston Clinical Session to be held Dec. 4-7, 1951. The 1952 Clinical Session will be held in Denver during the first week in December and the 1953 Clinical Session in St. Louis.

BLOOD BANKS

In its consideration of the report of the Committee on Blood Banks, a Reference Committee of the House of Delegates recommended that the Board of Trustees urge that a state committee on blood banks be established in all constituent associations, that these committees be advised of the necessity of full cooperation with all other agencies engaged in blood procurement programs, that they promptly develop a blood program and that a copy of the report of the Committee on Blood Banks which appeared in the Handbook and the supplementary report presented to the House be sent to the secretary of each constituent association for the information of its blood bank committee.

A SUCCESSFUL MEETING

Those who attended the fourth Clinical Session of the American Medical Association left with a feeling that much was accomplished. This was made possible by the cooperation of all participants, and to them goes much credit for their hard work and interest in the development of this meeting. Particular credit, however, should be accorded the physicians in Cleveland who responded on such short notice when arrangements for this meeting in Denver had to be canceled because of local difficulties. The Local Committee on Arrangements worked unceasingly to make the meeting a success. The Chairman, Dr. Fay A. Le Fevre and the members of the administrative and other committees that made the meeting possible deserve the warm praise given them by the House of Delegates as it closed its meeting.

GENERAL PRACTITIONER'S AWARD

At the recent annual clinical session in Cleveland, the House of Delegates of the American Medical Association awarded its Gold Medal "for exceptional service by a general practitioner" to Dr. Dean Sherwood Luce of Canton, Mass. His career is the prototype of that of thousands of general practitioners throughout the United States, who devote their lives to the care of the sick. The selection of a particular person for this honor, however, is carefully guarded by rules set up by the Association. Dr. Luce was born in Holliston, Mass., nearly 75 years ago, the son of a Yankee sea captain, who, after losing his ship and almost his life, opened a general store on Martha's Vineyard. Dr. Luce attended Phillips Andover Academy, and Harvard Medical School, returning to the island on week ends to look after the business. He graduated from Harvard and, after interning at the Long Island Hospital in New York, began to practice in Canton in 1905. He was still busy attending to his practice when notified of this award. For the formal presentation of the award before his fellow physicians, Dr. Luce flew to Cleveland. He has long been interested in medical organizational activities. He is a councilor of the Massachusetts Medical Society, a member of its Committee on Public Relations and a past president of the Norfolk District Medical Society and has been editor in chief of the official publication of that organization. Dr. Luce served as a captain in the Medical Corps of the Army in World War I and as a member of the Selective Service Board of his community in World War II. He has been a trustee of the Canton Public Library, a member of the Canton Board of Health, and the school physician of that city for more than 20 years. He is also a member of the senior staff of the Norwood Hospital in Norwood, which is in Norfolk County, as is Canton, his home town.

Dean Sherwood Luce, M.D.

NEW SUPPORT FOR MEDICAL EDUCATION

In an epoch-making statement, the Board of Trustees announced at the Cleveland meeting of the American Medical Association the appropriation of a half million dollars for 1951 as the nucleus of an annual fund to be raised for the aid of medical schools throughout the nation. This decision of the Board of Trustees was unanimously and enthusiastically adopted by the House of Delegates. The statement presented by Dr. Louis H. Bauer, Chairman of the Board, reads:

> The Board of Trustees of the American Medical Association is pleased to announce to the House of Delegates that it has appropriated a half million dollars out of its National Education Campaign Fund, which was raised to defend medical freedom, for the aid and support of medical schools which are in need of additional financing. This fund will be given to the medical schools for their unrestricted use in their basic training of future physicians. This appropriation to aid the medical schools has been made possible by the widespread public cooperation which the profession has received from the American people in its campaign against compulsory health insurance. The fight against socialized medicine must go on until this issue has been clearly and finally resolved, but the pressure for regimentation of the medical profession has greatly lessened, owing to the magnificent public support which we have received. The Board of Trustees, therefore, feels that it is keeping faith with the American people, who have given medicine such a splendid vote of confidence, when it contributes this amount to the medical schools of the nation.
>
> There is growing public awareness that federal subsidy has come to be a burden, not a bounty, for it is bringing intolerable increases in taxation and is dangerously increasing federal controls over our institutions and the lives of our people. American medicine feels very strongly that federal aid for medical schools should not be sought unless all other means of financing have been exhausted. The Board of Trustees announced yesterday its belief that funds for this purpose could be obtained from private sources—and as practical evidence of our sincerity of purpose, this appropriation has been made as the nucleus of a fund which we hope will be greatly augmented by contributions from many other sources.
>
> The Board hopes that this action will become a stimulus to other professions, industries, businesses, labor groups and private donors to contribute to this very important cause of protecting and advancing the interests of medical education and the public health. The American Medical Association urges all its members to contribute individually to this cause, and we hope that doctors will take the lead in securing contributions from other sources.
>
> Furthermore, the American Medical Association invites attention to the fact that it has been spending about a quarter of a million dollars a year for many years past to advance medical education through its Council on Medical Education and Hos-

pitals and other departments. This appropriation, voted today, for an entirely new purpose, is in addition to nearly $285,000 already budgeted for this work during 1951.

The nation's medical schools are of the greatest importance to every American citizen, and the American Medical Association has had the advancement of their standards as one of its main objectives for over 100 years. The Board of Trustees feels that, if all other organizations and individuals will render support of this worthy cause in accordance with their financial ability, not only will the financial security of medical schools be assured but their freedom will be protected.

Within hours after the Board's decision had been announced more than $6,600 was spontaneously pledged by individuals and several thousands from other sources. Details concerning the plan whereby others may give to the fund now are being worked out and will be announced in THE JOURNAL and through the *Secretary's Letter*, which is transmitted to all officers of the American Medical Association and of the state and county medical societies. Additional information may be obtained now from Dr. George F. Lull, Secretary of the Association, by those wishing to make an immediate contribution.

MILK-BORNE VIRUCIDE

Experimental evidence suggesting a milk-borne immunity against certain virus diseases was recently reported by Ratner,[1] Culbertson,[2] Curley [3] and others. Using murine poliomyelitis virus, Knox [4] of the Department of Bacteriology, Columbia University, confirms their evidence.

At various stages of gestation, 100 pregnant mice were inoculated orally with the murine virus. Eighteen viable litters were born to these inoculated mothers. Half the litter were reared by their own mothers, while others were reared by foster mothers, some of which were normal. Six additional litters were obtained from mothers not infected till after parturition, six litters from mothers of known immunity and four litters from normal mothers. Between the time of weaning and 44 days of age the young were tested for immunity by intranasal instillation of a 1 : 100 dilution of the murine virus. Older littermates and adults were tested by intraperitoneal inoculation with five times this dose. It was found that the immunity of the young was directly related to the immunity of the foster mother, rather than to the immunity of the natural mother. A nursing period of 10 days was sufficient to transfer complete protection against the test dose of murine virus.

Milk obtained from immune mothers was therefore pooled and tested for its in vitro capacity to neutralize murine poliomyelitis. While normal mouse milk had no detectable neutralizing power, milk from immune mice reduced the virulence of murine virus when tested in dilutions as high as 1 : 100 and completely neutralized the virus in a dilution of 1 : 10. The exact nature of the virucidal factor in immune mouse milk has not been determined.

REACTIONS TO DEXTROSE

Seibert [1] in 1923 demonstrated that the substance responsible for febrile reactions following administration of solutions by vein is a product of bacteria that exist in river water and in tap water. It is important to realize that it is not the bacteria that produce the reaction but their toxic products. Elimination of pyrogens, substances responsible for febrile reactions following administration of solutions by vein, is accomplished by a number of procedures, such as proper distillation and sterilization of glassware and tubing. Rademaker [2] stressed that the care of glassware and tubing constitutes the most important factor in elimination of such reactions. Some authors consider rapidity of infusion as being responsible for some of the shock symptoms of the postinfusion reaction.

However, according to Randolph and his co-workers [3] there remains a residue of reactions after all measures of control of pyrogens have been scrupulously adhered to and the speed of administration regulated. The fact that only a few patients have reactions, and that most do not, suggests that an individual idiosyncrasy or allergy plays a part. These authors stress that sensitivity to corn occurs as often as sensitivity to wheat, if not more so. It is therefore not surprising that there should be occasional reactions to intravenous injection of dextrose that is prepared from simple hydrolysis of cornstarch. These authors demonstrated that crystalline sugars prepared from cornstarch may cause intense allergic reactions when ingested by persons highly sensitive to corn. The rapidity of the onset and the severity of such clinical reactions suggest that the sugar is allergenic in the form administered rather than in some form occurring after ingestion. The specificity of these reactions is demonstrated by the fact that alpha-*d*-glucose prepared from beet sucrose fails to produce symptoms when ingested by the patient who is sensitive to corn and who reacts specifically to corn sucrose; conversely, glucose prepared from beet sucrose will produce allergic reactions when ingested by patients known to be sensitive to beets.

The authors were able to reproduce in five patients who showed great sensitivity on ingestion of corn and corn products similar allergic phenomena by intravenous injection of a 5 per cent dextrose solution. It therefore appears probable that some of the stormy postoperative courses may be explained on the basis of allergy to dextrose.

WASHINGTON NEWS

(From the Washington Office of the American Medical Association)

White House Conference on Children and Youth

In four crowded, hectic days in Washington, leaders in the nation's children and youth programs came to general agreement on what the young people need in health and other services Their findings are embodied in the report of the White House Conference on Children and Youth, attended by 6 000 official delegates and observers

"Children require, for their fullest development, full access to health, educational, recreational, social and religious services and programs directed toward the well-being of all they serve" This statement, taken from the preamble to recommendations, underlines all recommendations

The final plenary session came to these conclusions regarding the health of young people 1 More research is required on development and adjustment 2 All states should establish standards for the hospital care of mothers and children, "in order to assure the quality of care that modern science knows how to give" 3 All-inclusive minimum standards for day care center nursery schools and kindergardens should be established by state health or education departments 4 Prompt action should be taken at the national level to provide funds to supplement those of states and localities "to stimulate the early development of adequate local (public) health services throughout the country, 'particularly in view of mobilization' (A bill for federal aid to local public health units has passed the Senate but has been held up in a House committee 5 In developing new housing facilities, special attention should be given to health, recreational and social needs, and children of migrant workers should be given the same benefits as all other children One work section also came to the conclusion that "child health and welfare services are uneven in distribution and lacking in continuity and quality Yet adequate services of this kind are basic for the development of healthy personality" Another section was even more critical "Present health services have many inadequacies, particularly in relation to furthering healthy personality development in children and youth Many now rendering such services do not fully understand or give attention to the dignity and emotions of the individual, which are necessary to healthy personality development " The same section also commented, " success of mobilization is to an important degree dependent on provision of adequate health services to our mothers, children and youth" Another section cited the need for adequate treatment programs for handicapped children, and a further expansion of health services for children in general

In their final draft, recommendations omitted such controversial subjects as President Truman's national compulsory health insurance plan, aid to medical education and permanent and total disability insurance However, these and almost every other subject in the health field were heatedly debated in work groups A resolution endorsing compulsory health insurance came out of one work group, but did not reach the floor Another called for permanent and total disability insurance as essential to the security of children, but this, too, was deleted before the resolution was presented for action by the plenary session

Conference Notes

The 6,000 delegates to the conference made it one of the biggest meetings ever held in Washington, attendance was more than double that at the last White House Conference on Children and Youth Invitations were issued to about 400 federal officials Work groups were assigned topics that cut across professional lines, thereby insuring a variety of expression With a two year build up for the conference, demand for invitations was so great that a cutoff had to be imposed early in November No specific "health" or "medical" topic was assigned, but reference to health and medical problems appeared in many of the recommendations Delegates all invited as individuals with particular interest in the problems of children, were selected mainly from three sources—national organizations working with children and youth, state organizations and youth participation organizations This was the first time young people were asked to attend the Conference or participate in its planning One hundred and eighty physicians attended, over 100,000 persons helped in preparations for meeting, 500 youth delegates participating Subject matter of work groups ranged from infancy to young adulthood, from effects of the atomic bomb to cheating in school, from discrimination to television On Selective Service, Dr William C Menninger, Menninger Foundation, had this to say "Selective Service always discriminates, as illustrated by the fact that psychological tests designed to eliminate 13 per cent are actually rejecting 24 per cent of those available for service" Referring to the current deferment of the top 50 per cent of college students, he said, "The men in service would then bear the stigma of low scholastic ability, and academic standards vary, so that the 'lower' group in one college would be considered 'upper' in others" The 300 delegates attending a panel on effects of mass communications unanimously recommended that FCC allocate certain remaining television channels to educational institutions

Stockpiling of Medical Equipment

American mayors, testifying on Civil Defense legislation before the Senate Armed Services Committee, urged that the federal government act promptly to start building up regional stockpiles of medical equipment On this the mayors and civil defense officials are in agreement, and legislation appropriating $400,000,000 to buy medical and engineering supplies is before the committee However, on two other important points the mayors are completely at odds with the federal program

1 By unanimous vote, the American Municipal Association, made up of mayors, recommended that civil defense be made part of the Defense Department, but under civilian control This is unlikely without a reversal of direction, in view of the fact that an independent Federal Civil Defense Administration was set up by President Truman on December 1 and already is functioning The Senate committee has before it a bill (S 4219) that would establish the administration by statute and give it unprecedented power to meet disaster problems

2 In the same recommendation, the mayors urged that the federal civil defense organization establish and maintain direct ties with cities and communities, to assure them up to-the-minute information and guidance in their preparations In reply, James J Wadsworth, deputy administrator of FCDA, pointed out that the whole civil defense program is based on delegation of responsibility, from federal to state and from state to local He emphasized that federal civil defense authorities already have put out vast amounts of information in the form of pamphlets and booklets Particularly, he requested the mayors to give the following information to citizens who ask "What can I do" "The Red Cross has mobilized its facilities and chapters to carry out three major activities in which everyone can take part These are the first aid program, in which some 20,000,000 persons should be trained as rapidly as possible, the national blood program, in which the Red Cross will coordinate the efforts of all interested agencies in developing a realistic program of mass blood procurement, and the nurses aid and home nursing training, which will be carried out on a large scale"

The mayor s request for immediate action on medical stockpiles was presented to the committee by Mayor John B Hynes of Boston, who also urged that medical equipment be standardized Mayor Albert E Cobo of Detroit supported this demand, saying the cities had a right to know immediately what the federal government is going to do about stockpiling and standardizing medical as well as other supplies. Several other mayors voiced the same general opinions.

In earlier testimony before another Congressional committee, W. Stuart Symington, chairman of the National Security Resources Board, emphasized repeatedly that primary responsibility rested with states and communities. He said, "The greatest pressure of the operating load in civil defense rests squarely on the shoulders of our state and local governments. . . . The Civil Defense Office (at that time in N.S.R.B.) has pounded home constantly the theme that our states and cities must meet squarely the problems of heading up the grave and complex program which the international situation has imposed on every state and almost every city in our country. . . . (this) is the greatest challenge ever faced by our state and local governments. . . ."

Refilling of Prescriptions

Announcement of a proposed change in federal regulations on refilling of prescriptions has brought the whole subject again under discussion, this time with the probability of concrete developments. Federal Security Administrator Oscar Ewing has allowed 30 days for comments or protests to be filed, with the new regulations not to be put into effect until objections have been considered. The effect of the change, as now proposed, would be to allow pharmacists to refill prescriptions containing "over the counter drugs" without either written or oral prescription from the physicians. There would be no relaxation regarding so-called potent or prescription drugs, which still would have to carry the label "Caution: To be dispensed only by or on the prescription of a physician." FSA said, "We will continue to press legal action against those few pharmacists who endanger their customers' lives by selling these toxic drugs without prescription or on unauthorized refill." The complete text of the proposed regulation appears in the *Federal Register* for December 6.

Announcement that the change was contemplated came after the American Pharmaceutical Association had called for a public hearing on the whole issue of refilling prescriptions. Instead, FSA drew up the new regulations and allowed 30 days for comment or protests. As a consequence, objections from the Association or any other interested groups will be filed in writing rather than presented in open hearing. A spokesman for the American Pharmaceutical Association said that, if the regulations as finally drafted are not satisfactory, the association will go to court to enjoin FSA from putting them into effect.

Meanwhile, legislation to revise federal statutes on prescriptions appears to be definitely dead for this Congress. The Durham-Humphrey bill (H. R. 8904 and S. 3852) has two principal provisions: 1. Except for narcotics, "prescription legend" drugs could be filled on oral order from the physician, but he would be required to confirm the prescription in writing within 72 hours. 2. Clear definition would be made of drugs that would have to carry the prescription legend and "over-the-counter" drugs. Prescriptions for the latter could be refilled without reference to the physician. This bill has the support of the Food and Drug Administration, Federal Trade Commission and the retail druggists, but some of its provisions are opposed by the American Pharmaceutical Association.

Atomic Energy Commission Fellowships

The Atomic Energy Commission announces a total of 325 fellowships for the 1951-1952 academic year, divided as follows: 150 predoctoral in physical sciences; 100 in biologic sciences; 30 postdoctoral fellowships in physical sciences and 45 in biologic and medical sciences. The program will be administered by the Institute of Nuclear Studies, Inc., of Oak Ridge, with the National Research Council screening applicants. Final determination of fellows will be made by a national fellowship board to be appointed by the institute. Some type of security clearance is required for all fellowships. Predoctoral fellows receive $1,600 and postdoctoral $3,000, plus dependency allowances. AEC prefers to have postdoctoral fellowships served at an institution other than the one from which the fellow received his doctor's degree.

Chemicals in Foods

Recommendations for new legislation governing use of new chemicals in or on foods are almost certain to be made as a result of three months of intermittent hearings conducted by the House Select Committee on Chemicals in Foods. At this writing only one proposed bill is before the committee, that submitted by C. W. Crawford, Deputy Commissioner of foods and drugs, Food and Drug Administration, but committee members are expected to have some ideas of their own to submit to Congress. Mr. Crawford's bill would require producers of insecticides and other chemicals and preservatives for fresh and canned foods to submit their product to a specific series of tests before putting them on the market. Several witnesses have expressed the opinion that the residue from dusting and spraying compounds in some cases is dangerous to humans and that some other types of chemicals used in processing or packaging foods also are a hazard.

In the course of the hearings, Committee Counsel Vincent Kleinfeld complained that some representatives of the food industry have appeared reluctant to testify. The committee has not used its power of subpoena, but Mr. Kleinfeld said a few letters "requesting" attendance had been sent out when earlier invitations were ignored. Last week a group of agronomists, representing several universities and colleges, testified that chemical fertilizers if used properly are not harmful to man. Their argument was similar to that advanced earlier by a representative of producers of these agricultural chemicals, namely, that existing legislation is sufficient to protect the public and that, if there is any ground for concern, it is in the way the present laws are being enforced. Views of the food chemical industry (chemicals added to foods) were presented by Dr. John Foulgar of E. I. du Pont de Nemours & Co., supported by several other technical witnesses. He urged the committee to consider the disadvantages as well as the advantages of any new laws and stressed that many of these chemicals are important to the national diet. He advised the committee to make certain that any new test methods or standards required be reasonable and practical, as well as effective in protecting the health of the country. He said that, if the practical aspect of investigations were ignored, one result might be a slackening of efforts to develop new and improved ingredients. Dr. Foulgar suggested that the committee consider amendment of the Food, Drug and Cosmetic Act to require notice to Food and Drug Administration of intent to add to a food an ingredient not previously used in that food.

Notes

The full text of Executive Order 10186, establishing a Civil Defense Administration, appears in the *Federal Register* of December 5. The administration has less power under the executive order than under the proposed law. . . . "Sourcebook on Atomic Energy," the latest Atomic Energy Commission publication, is a 546 page book giving a review of basic nonsecret atomic energy information. . . . Bills to insure greatest possible distribution of N.S.R.B.'s pamphlet, "Survival Under Atomic Attack," are now before both House and Senate. N.S.R.B. has distributed over a quarter of a million copies. Copies may be purchased from the Superintendent of Documents, Government Printing Office, Washington 25, D. C., for 10 cents each. Incidentally, the latest word is that the health service manual for civil defense will be mailed to state Civil Defense directors before the first of the year. . . . The Senate subcommittee investigating health services has figures from commercial insurance companies, Blue Cross and Blue Shield. The committee is analyzing the statistics and has asked these groups for their opinions, which also will be analyzed for the report. . . . E. Roland Harriman has officially taken office as the new president of the American National Red Cross.

GOVERNMENT SERVICES

Army

Training Program Provided Physicians in the Emergency

At the beginning of the Korean conflict, only about 190 Army physicians were on duty in the entire Far East Command comprising Japan, Okinawa, Guam, the Philippines and Korea. As the troops in that area required a much larger number of physicians, the situation quickly became an emergency. Appeals were made to reserve officers, but of more than 3,000 who received letters, only 40 volunteered for immediate active duty. The Surgeon General's office considered next the young physicians who were serving in residency programs. The five large Army teaching hospitals already had small permanent and residency staffs, so that all residents could not be taken away from these hospitals. It was decided to reduce each service to the minimum necessary for the continuation of medical care in the hospital. This was done, and 132 residents, 101 young physicians who had just finished their internships and 89 civilian residents were flown to the Far East. The military stations throughout the United States were further depleted of medical officers, and they, too, were flown to the Far East, making in all, as of Nov. 7, 1950, about 750 medical officers in the Far East Command. The civilian residents were taken only after telegrams had been sent to the superintendents of the hospitals in which they were located requesting the release of these civilian residents as soon as possible. With few exceptions all agreed to assist. The value of the residency training program, which had been established after World War II, was indeed great in this emergency. The Army Medical Service was thus enabled to furnish medical officers promptly in all of the required specialties, and the medical care provided to the sick and wounded was creditable in every respect. In fact, according to Brig. Gen. Paul I. Robinson of the Surgeon General's office, in his address before the New England Post Graduate Assembly, Boston, Nov. 7, 1950, "There is every indication that an extraordinary record is in the making." General Robinson said that the wounded-in-action in the first three months of the Korean campaign equaled the number of American wounded in the first one and a half years of our participation in World War II. Nevertheless, the fatality rate for wounded soldiers reaching treatment centers, he said, will probably be less than half the World War II rate, which was 4.5 per cent.

Medical Draft Commission Deadline

In response to numerous inquiries relative to the final date on which draft eligible physicians may receive preinduction reserve commissions, Major Gen. Raymond W. Bliss, the Surgeon General, emphasized November 24 that the mechanics of processing applications preclude the guarantee of a commission to a registrant if he applies after receiving his induction notice. This commission deadline, General Bliss explained, is the result of administrative considerations. Section 5 of Public Law 779, 81st Congress, simply provides that "no person inducted under the provisions of this Act shall be entitled to the benefits of the provisions of Section 203 of Public Law 351, 81st Congress." However, for physicians and dentists to qualify as volunteers, and thus for the special professional pay authorized under Public Law 351, all processing required for a reserve commission must be accomplished and appointment made prior to induction.

"Because of the work load involved in processing an application for reserve commission, and the controls necessary for a decentralized Selective Service system, as well as a decentralized Army appointment system, we simply cannot guarantee that a registrant can receive his commission in time if he applies after he has received his induction notice," General Bliss said. "This, of course, does not preclude any registrant's applying for his commission after he has received his induction notice, and, if he receives a commission before actual induction, he is entitled to all the benefits provided for commissioned officers."

Personal

Col. Floyd L. Wergeland (MC) chief, Education and Training Division, Office of the Surgeon General, was honored by the College of Medical Evangelists, Loma Linda, Calif., on October 15, when he received the "Alumnus of the Year Award" at the annual alumni banquet in Los Angeles.

Navy

Admiral Boone Retires

Rear Admiral Joel T. Boone (MC), Inspector General, Medical Activities, retired on Dec. 1, 1950, with the rank of vice admiral after 36½ years of active duty in the Navy. In 1914 Admiral Boone entered the Navy as a lieutenant (junior grade). He served with the Marine Expeditionary Forces in Haiti and in 1916 participated in quelling the "Caco" (bandit) uprising, for which he received a Letter of Commendation from the Secretary of the Navy for "coolness under fire." In World War I, he served in France with the Second Army Division, participating in several major battles. For this service in France he was awarded the Medal of Honor by Congress for extraordinary heroism, conspicuous gallantry and intrepidity in conflict with the enemy.

During World War II Admiral Boone was Fleet Medical Officer. He was selected to be one of three officers to liberate Allied prisoners of war in Japan prior to the military occupation of that country and was the Naval Medical Corps representative at the surrender ceremonies of the Japanese aboard the *USS Missouri* on Sept. 2, 1945. He represented the Navy for three years as Director, Bureau of Naval Affairs, American Red Cross. In 1946 he was assigned as Medical Advisor to the Federal Coal Mines Administrator and as Director of the Medical Survey of the Coal Industry. In 1948-1949 he was Executive Secretary of the Secretary of Defense's Committee on Medical and Hospital Services of the Armed Forces. In 1949, Admiral Boone reported to the Secretary of Defense, having been appointed Chief of Joint Plans and Action Division, Office of Medical Services. During 1949 he served as president of the Association of Military Surgeons. Admiral Boone is the most decorated medical officer in the history of the Navy. He also had the honor of being physician to three Presidents, the late Presidents Warren G. Harding and Calvin Coolidge and later to President Herbert Hoover. Admiral and Mrs. Boone will reside in Washington for the immediate present at 4000 Cathedral Avenue, Northwest.

Personal

Rear Admiral Lamont Pugh, Deputy Surgeon General, has been elected president of the Washington Chapter of the University of Virginia Alumni Association.

Captains James R. McIntosh (MC, USNR), Bloomington, Ill., Clement C. Troensegaard (MC, USNR), Berkeley, Calif., and Lieut. (jg) Dwight M. Frost (MC, USNR) of Milwaukee, have been recalled to active duty at their own request.

Comdr. Harold A. Lyons (MC) has been appointed clinical assistant professor of medicine at the University of the State of New York College of Medicine.

Air Force

Dr. Boothby at Randolph Field

Dr. Walter M. Boothby, a professor emeritus of the Mayo Foundation, has joined the professional staff of the School of Aviation Medicine, Randolph Field, Texas, as research advisor. Dr. Boothby arrived at the school from Sweden, where for two years he had been advisor on research in aviation medicine and physiology to the Swedish Aviation Medicine Council at the University of Lund. While abroad he also appeared as guest lecturer at the universities of Aarhus, in Denmark, and Oxford and Cambridge, in England. At the Mayo Foundation Dr. Boothby was professor of experimental metabolism and, while there, organized the Mayo Aeromedical unit for research in aviation medicine. He is one of the original fellows of the Aero Medical Association, and is a fellow of the American College of Surgeons and of the American College of Physicians. During his long career Dr. Boothby has been instructor of anatomy at Harvard University Medical School, head of the Metabolism and Respiration Laboratories at Peter Bent Brigham Hospital, Boston, and chief of the Section on Metabolic Research at the Mayo Clinic. In World War I he was director of the First Corps Anti-Gas School and later instructor in the Army Medical School at Lange, France. He was at the front during the battles of St. Mihiel and the Argonne as chief of a surgical team. In 1938 he was a joint recipient of the Collier Trophy, in which he was cited by President Roosevelt for his contribution to aviation medicine in general and research on pilot fatigue in particular. He is a native of Boston and a graduate of Harvard University Medical School.

Gorgas Medal Presented to Major General Grow

At the annual dinner of the Association of Military Surgeons of the United States in New York, November 10, the Gorgas Medal was presented to Major Gen. Malcolm C. Grow (retired), former surgeon general of the U. S. Air Force. The medal and a $500 cash award was presented by Mr. H. W. Blades, executive vice president of Wyeth Incorporated, which pharmaceutical house established the medal in 1942 in honor of Surgeon General William Crawford Gorgas, whose work in preventive medicine made possible the construction of the Panama Canal. The recipient of the award is chosen annually by the Association of Military Surgeons.

According to the citation, General Grow "initiated, developed and made final arrangements for the employment of body armor to protect air force combat crews. He developed and put into use a device to protect gunners from wind blast; he developed electrically heated clothing, casualty bags for the wounded and wind and fire resistant face and neck protectors." General Grow was graduated from Jefferson Medical College in 1909. He retired on Nov. 30, 1949, after more than 31 years of military medical service.

Among the decorations and honors he holds are the Legion of Merit, Distinguished Service Medal, Bronze Star and French Legion of Honor in the rank of Chevalier, the Most Excellent Order of the British Empire, degree of Honorary Commander and the John Jeffrier Award. In 1949, General Grow was certified by the American Board of Preventive Medicine and Public Health.

Medical Supplies Dropped by Parachute

The 307th Airborne Medical Battalion, 82 Airborne Division, on October 26, pioneered the first heavy drop by parachute of major medical equipment. With no precedent to guide them, the 307th in conjunction with the Airborne Section of Army Field Forces Test Board no. 1, loaded a complete surgical operating unit on a heavy drop skid and dropped it from the rear of a C-82 aircraft. Another skid consisting of two complete hospital ward tents was also loaded and dropped. The first load landed without damaging a single item of equipment, which included such fragile items as thermometers, test tubes, a microscope and many delicate surgical instruments. The equipment, most of which had never been dropped by parachute before, included such items as a four section hospital tent, an autoclave (steam sterilizer) weighing 350 pounds, a complete field laboratory, two operating room lamps with batteries and a small generator, litters, blankets, surgical gowns and all the drugs needed for an extended stay in the field. The entire load weighed 4,500 pounds net. The second skid consisting of two hospital ward tents, with equipment necessary to care for all types of patients landed without mishap.

Veterans Administration

Benefits Authorized for World War II Veterans

The "Fact Sheet" released by the Veterans Administration Nov. 15, 1950, points out that the following medical and domiciliary benefits are authorized for World War II veterans:

Hospitalization.—World War II veterans, if discharged or separated under conditions other than dishonorable, are entitled to VA hospital treatment, under the following priority system: first, emergency cases; second, those suffering from injuries or diseases incurred or aggravated in line of duty during wartime service and third, those who state under oath that they are unable to pay hospital charges for treatment of non-service-connected disabilities or illnesses. These veterans, if not in the emergency category, must wait until a bed becomes available.

Emergency patients may be taken directly to the nearest VA hospital. If possible, the veteran, or someone acting for him or her, should communicate with VA by telephone or telegraph. In all other cases, the veteran, or his nearest relative, guardian or representative, should fill in the proper form for hospital care. These forms are available at any VA office.

If admission to a VA hospital or home has been approved, government transportation may be provided as follows:

1. Hospitals: To the hospital and, on completion of treatment in service-connected cases, to his or her home. This service may be provided for non-service-connected cases if they are unable to pay for the transportation.
2. Homes: To a VA domiciliary home.

Domiciliary care is designed to provide a "home" for veterans who have a chronic condition that incapacitates them from earning a living and who require minimal medical attention. Requirements for admission for domiciliary care are essentially the same as for hospital treatment. Transportation at government expense as a rule is provided only for the initial admission. The veteran, or his nearest relative, guardian or representative, should obtain preadmission approval from the nearest VA installation having facilities for domiciliary care.

Outpatient medical care is available for veterans in need of treatment for service-connected disabilities. Under this plan, eligible World War II veterans may receive treatment at VA hospitals or other field stations furnishing medical treatment or from approved private physicians. Each veteran's eligibility must be determined by VA before treatment of this type can be authorized. Necessary drugs may be obtained from "home town" druggists at government expense by veterans who are authorized to report to private physicians for treatment.

Personal

Dr. Franklin G. Ebaugh, professor of psychiatry, University of Colorado, conducted a two day seminar on the treatment of emotional disorders at the Veterans Administration Hospital, American Lake, Wash., October 2-3.

Dr. Knut Lindblom, Stockholm, Sweden, addressed the staff of the Crile Veterans Administration Hospital, Cleveland, October 2, 1950 on "Arthrography of the Knee" and "Myelography and Disk Puncture."

Dr. John J. Tyson has been appointed manager of the VA hospital in Omaha, which is scheduled to admit its first patients in November.

MEDICAL NEWS

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

Tenth Anniversary of Poliomyelitis Center.—A conference commemorating the tenth anniversary of Tuskegee Institute's treatment and training center for infantile paralysis was held November 27-28 in Tuskegee. Basil O'Connor, New York, president, National Foundation for Infantile Paralysis, was among the speakers who addressed 300 delegates and volunteer workers representing the foundation's chapters in various states. The celebration also served as a precampaign conference for the 1951 March of Dimes. Tuskegee's infantile paralysis center for Negro poliomyelitis patients and medical workers was established through a grant from the foundation. It is a three story brick building, a separate wing of the John A. Andrew Memorial Hospital, with which its work is coordinated.

CALIFORNIA

Short Poliomyelitis Courses.—Orthopaedic Hospital, Los Angeles, will give three short courses in poliomyelitis for physicians during 1951, aided by a grant from the National Foundation for Infantile Paralysis. Covering all phases of patient care, the courses will emphasize teamwork by professional services. New apparatus and methods for acute poliomyelitis treatment will be presented through cooperation with the Los Angeles General Hospital. Classes are scheduled for February 12-15, May 21-24 and October 22-25. Information may be obtained and enrolment made through C. L. Lowman, M.D., 2400 S. Flower Street, Los Angeles 7.

Voters Approve Release of Animals for Research.—The voters of Los Angeles on November 7 approved a proposition releasing an estimated 50,000 unwanted unclaimed dogs and cats from city pounds to qualified research institutions that are certified by the city health officer and inspected by the Department of Animal Regulation. A citizens committee conducted a campaign jointly with the Medical Research Society of Southern California, while the San Francisco County Medical Society contributed financially. Among the defense projects which have been hampered by a lack of animals for research is an Atomic Energy Commission program at the University of California School of Medicine, Los Angeles, to develop protective treatment against radiation effects of atomic bombs. A vital Navy aviation program to improve safety of high altitude jet flight was slowed down. Individual physicians also contributed to the successful campaign by urging their patients to vote for "Proposition C." Posters were placed in waiting rooms and drug stores. A tabloid newspaper captioned "Citizens Committee News for Yes on Proposition C" was widely distributed.

COLORADO

University Appointment.—Dr. John A. Frank has been appointed assistant professor of psychiatry in the University of Colorado department of medicine and a senior staff physician at the Colorado Psychopathic Hospital, Denver. One of his duties is to take charge of the 1927 Colorado law cases, that is, the examination of criminals who are making pleas of insanity. Dr. Frank comes to the university from Bellevue Hospital in New York, where he did similar work. He has been on the faculty of New York University since 1944.

CONNECTICUT

Personal.—Dr. Samuel C. Harvey, New Haven, has been appointed state director for the selection of physicians under the recently enacted Doctor-Draft Act. Serving with Dr. Harvey will be Dr. Stanley H. Osborn, state commissioner of health, and William R. Dunleavy, New Haven, dental advisor.

Dr. Murdock Honored.—Dr. Thomas P. Murdock, Meriden, member of the American Medical Association's Board of Trustees, was guest of honor at a testimonial dinner in New Haven November 29, in recognition of his many years of service to the medical profession. The event was held at the New Haven Country Club. Among the speakers were Dr. Louis H. Bauer, New York, Chairman of the American Medical Association's Board of Trustees; Dr. Edward R. Cunniffe, chairman, Judicial Council of the Association; Dr. Hart E. Van Riper, New York; Dr. Morris Fishbein, Chicago, and Dr. Creighton Barker, executive secretary, Connecticut State Medical Society. Dr. Thomas J. Danaher, Torrington, president of the state medical society, presided. Dr. Murdock is a past president of the state medical society and the New Haven County Medical Association. For several years he has been a member of the House of Delegates of the American Medical Association. In 1949 he was chairman of the A. M. A. Committee to Survey Nursing Services in the United States. He was a member of the Connecticut Medical Examining Board for 15 years.

ILLINOIS

Narcotic Violation.—Dr. John W. Long of Robinson recently pleaded nolo contendere at Danville to an indictment charging violation of the federal narcotic law and on September 11 was fined $500.

Chicago

Personal.—Col. Arnold D. Tuttle (MC, USA, retired), now medical director for United Air Lines, gave the graduation address for the aviation medical examiner class, School of Aviation Medicine, Randolph Field, Texas, December 2. Colonel Tuttle is a former commandant of the School of Aviation Medicine.

Society News.—The Chicago Society of Physical Medicine and Rehabilitation will meet January 24 at 8:00 p. m. in the Medical Center, Y. M. C. A., 1804 West Congress Street. Arthur H. Steinhaus, Ph.D., professor of physiology, George Williams College, Chicago, will speak on "Physiology of Exercise." Professional personnel and their guests are welcome.

Committee to Select New Department Head.—Dr. Warren H. Cole has been appointed chairman of a committee that will select a new head for the department of medicine at the University of Illinois College of Medicine and the university's Research and Educational Hospitals. Dr. Robert W. Keeton, present head of the department of medicine, will reach the retirement age of 68 during the present academic year. On the committee with Dr. Cole are Drs. Granville A. Bennett, George M. Hass, Francis J. Gerty, Henry G. Poncher, Francis E. Senear and George E. Wakerlin.

Chicago Medical School Appointments.—Dr. Herman Josephy, attending neuropathologist at the Chicago State Hospital, has been appointed associate professor of neurology at the Chicago Medical School. From 1914 until 1933 when he left his native Germany, Dr. Josephy was a physician at the Psychiatric Hospital in Hamburg, and from 1924 to 1933 he was an associate professor of neurology at the University of Hamburg. Harold Elishewitz, Ph.D., has been appointed assistant professor of parasitology in the department of microbiology and public health. He entered the research and development branch of the Quartermaster General, Research and Development, U. S. War Department, in Washington, D. C., in 1943 and served also as recording secretary of the National Research Council Committee on Insecticides and Insect Repellents. The following two years he was associated with the Pan American Sanitary Bureau in South America and Southern Mexico.

New Program for Nurses at Northwestern.—Northwestern University Medical School has announced a new program for nurses that offers a Bachelor of Science degree in nursing in addition to the diploma in nursing. Candidates for the degree must have 90 quarter hours in an accredited university and must complete three calendar years in one of the schools of nursing affiliated with Northwestern University. These are Wesley Memorial Hospital and Passavant Memorial Hospital, both located on the Chicago Campus, and Evanston Hospital. Under the new program residence in Northwestern's College of Liberal Arts is not required. Credit from any accredited university will be accepted, but work in English, chemistry and biology is required. The new program, formulated by the Council on Nursing Education, was requested by the Northwestern Senate last June. Dr. John H. Annegers Jr., assistant professor of physiology, is the coordinator and director of the program in nursing, under Dr. Van Dellen, director of the newly created Division of Auxiliary Medical Services.

INDIANA

Physicians in General Assembly.—When the 87th Indiana General Assembly opens, on January 4, three physicians will be among its members: Dr. William M. Cockrum of Evansville, a delegate from Indiana to the American Medical Association House of Delegates, and Dr. Otis A. Koop of Anderson, who were elected to the House of Representatives last month, and Dr. Walter F. Kelly of Indianapolis, a holdover senator.

IOWA

Fellowships in Basic Sciences.—Two fellowships supported by the Medical Service Funds of the State University of Iowa College of Medicine are being offered to graduates in medicine who contemplate academic careers. These are offered on the basis of half-time teaching and half-time research in any of the following departments: anatomy, bacteriology, biochemistry, pathology, pharmacology, physiology and hygiene and public health. Candidates may or may not have had clinical internships. Clinical residency trainees are acceptable if they wish to complement or interrupt a clinical residency program. Graduates of any approved medical school may apply. The salary will be $3,600 on a 12 month basis for those who are unmarried and $4,000 per year for those who are married. Application blanks may be obtained from the Office of the Dean, College of Medicine, State University of Iowa, Iowa City. Applications should be submitted to the same address on or before April 1, 1951.

KENTUCKY

Mobile Water Laboratory.—The State Health Department has a new $12,000 laboratory trailer fully equipped to take pollution tests along the Ohio River as part of a six state survey.

Cancer Society.—At the annual achievement dinner of the Kentucky Division of the American Cancer Society in Louisville November 14, Kenneth C. D. Hickman, Ph.D., of the Eastman Kodak Company, Rochester, N. Y., spoke on "Time and the Cancer Problem." The dinner honoring the 120 volunteer county organizations was attended by 250 workers throughout the state.

Personals.—At a meeting of the State Medical Research Commission November 16, Dr. Carl C. Howard, Glasgow, was reelected chairman, a position which he has held since the group was organized in 1948.——Dr. Harold M. Kelso, Louisville, has resigned as director of county health work of the State Department of Health, effective January 1. He will assume his former position of assistant city health officer, Knoxville, Tenn.

MASSACHUSETTS

Putnam Fellowship Open.—The Helen Putnam Fellowship for advanced research in genetics or mental health, open to women scholars who have a doctorate, is being offered by Radcliffe College for the academic year 1951-1952. The award carries a stipend of $2,800 a year with the possibility of renewal. Applicants are asked to submit a plan of research. Preference will be given those whose research is already in progress. Applications should be returned to the Secretary of the Graduate School, Radcliffe College, Cambridge, not later than April 1, 1951.

MICHIGAN

Pilot Blood-Typing Program.—Nurses, medical technologists and clerks began the first week of this month a project to type blood of students and faculty members at Wayne University, Detroit. The program, tentatively scheduled to run until the Christmas holidays, is part of a larger project being conducted by the state Office of Civilian Defense. The program is a "pilot study to see what problems are involved in a cooperative study of this kind." A uniform method of typing has been adopted by the whole state. Michigan cities taking part in the project are Jackson, Birmingham and Ypsilanti.

MISSOURI

General Practitioners Study Club.—The following programs for 1951 featuring local physicians have been arranged by the General Practitioners Study Club of Greater St. Louis:

Jan. 17, Norman Tobias, Office Treatment of Common Skin Diseases.
Feb. 21, Robert W. Bartlett, Differential Diagnosis and Treatment of Pain in the Right Upper Abdominal Quadrant.
March 21, W. G. Klingberg, Genitourinary Conditions in Childhood.
April 18, Robert E. Bruner, Early Diagnosis and Treatment in Cerebral Palsy.

NEVADA

Society Election.—The Nevada State Medical Association at its convention in October installed Dr. Walter F. Quinn of Ruth as president. Dr. J. Vernon Cantlon, Reno, was chosen president-elect; Dr. Leslie A. Moren, Elko, first vice president, and Dr. Clare W. Woodbury, Las Vegas, second vice president. The next annual meeting of the association will be held in Reno in October 1951.

NEW YORK

Postgraduate Instruction.—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged two lectures for the Jefferson County Medical Society, meeting in the Black River Valley Club, Watertown, at 6:30 p. m.

Dec. 19, Robert B. Burtch, Alexandria Bay, N. Y., and D. Naldrett White, Kingston, Canada, Recent Viral Disease Epidemic at Alexandria Bay.
Jan. 18, Nathaniel Kwit, New York, Management of Congestive Failure.

Dr. Small to Head Psychiatry Department.—Dr. S. Mouchly Small, New York, has been appointed head of the department of psychiatry at the University of Buffalo School of Medicine. He will also be director of psychiatry at Meyer Memorial Hospital. Dr. Small has been assistant resident in psychiatry at the Institute of Human Relations in New Haven, Conn., assistant resident and resident psychiatrist at the Payne Whitney Psychiatric Clinic of New York Hospital, instructor in psychiatry at Cornell and assistant medical director and consultant in psychiatry, National Hospital for Speech Disorders, New York. From 1943 to 1947 he was consultant in psychiatry to the American Cyanamid Corp., serving simultaneously as consultant in psychiatry and neurology at Vassar College. He was a psychiatrist at New York Hospital Rehabilitation Clinic from 1944 to 1946. Since 1947 Dr. Small has been neuropsychiatric consultant to the Surgeon General of the U. S. Army, serving also as consultant and lecturer to the Veterans Administration and lecturer at Columbia University College of Physicians and Surgeons.

New York City

Fourth Harvey Lecture.—Alfred E. Mirsky, Ph.D., member of the Rockefeller Institute for Medical Research, will deliver the Fourth Harvey Lecture of the current series at the New York Academy of Medicine on December 21, on "Chemical Aspects of the Cell Nucleus."

Personals.—Dr. Emil Froeschels has been made head of the new clinic for speech and voice disturbances at Beth David Hospital.——Dr. James W. Smith, assistant clinical professor of ophthalmology, has been promoted to clinical professor of ophthalmology at the Post Graduate Medical School of the New York University of Bellevue Medical Center.

Cancer Memorial Fund Check for Research.—A check for $100,000, from funds collected for the Damon Runyon Memorial Fund, was presented to the Sloan-Kettering Institute for Cancer Research at a luncheon November 10. The check was given to Dr. Cornelius P. Rhoads, director of the Memorial Center for Cancer and Allied Diseases, with which the institute is affiliated.

Friday Afternoon Lectures.—The twenty-fourth series of Friday Afternoon Lectures being given by the New York Academy of Medicine at 4:30 p. m. is open to physicians and to medical students. Lectures through February in the series are as follows:

Dec. 15, Oskar Diethelm, New York, Advances in Treatment of Chronic Alcoholism.
Jan. 5, J. Lester Gabrilove, New York, Virilizing Syndrome in Man.
Jan. 12, Sydney Farber, Boston, Newer Agents in the Treatment of Acute Leukemia.
Jan. 9, André Cournand, New York, Newer Methods in Diagnosis of Congenital Cardiac Anomalies.
Jan. 26, Judah L. Ebin, New York, Surgical Treatment of Parkinsonism, Indications and Results.
Feb. 2, William J. Grace, New York, Experimental Study of Chronic Ulcerative Colitis.
Feb. 9, Robert S. Hotchkiss, New York, Diagnosis of Testicular Deficiency States.
Feb. 16, Arthur H. Blakemore, New York, Shunt Operations for Treatment of Portal Hypertension with Special Reference to Cirrhosis of the Liver.

Pay Blue Cross Subscription with Rent.—With the enrolment of 252 residents of Bell Park Gardens, veteran's cooperative housing project in Queens, New York's Blue Cross Plan established a precedent by arranging for subscription fees to be paid along with the rent. The veterans and their family dependents were eligible for enrolment beginning December 1. It is reported that at least an equal number of families living in Bell Park Gardens are already receiving Blue Cross coverage through groups in organizations where they are employed. Associated Hospital Service, New York's Blue Cross Plan, is a nonprofit, hospital-sponsored organization, which now serves 4,500,000 persons in the Greater New York area.

Admissions Committee Reorganized.—The Office of Admissions of the New York University College of Medicine has been reorganized. Dr. H. Sherwood Lawrence has been appointed secretary of the Committee on Admissions. In order to allow the most thorough consideration of the qualifications of candidates seeking admission, enlargement of the college's Office of Admissions became necessary because of the problems arising from multiple applications for entry into medical schools. More than 2,500 applications had been made for the 125 places in the college's first year class. Almost every candidate applied to several schools, Dean Currier McEwen said, while some were known to have applied to as many as 40 schools at once. Dr. Lawrence is an instructor in medicine.

TEXAS

A. O. A. Chapter at Southwestern.—At the installation dinner of the Alpha Omega Alpha honorary medical society chapter at Southwestern Medical College, Dallas, November 10, Chauncey D. Leake, Ph.D., Galveston, spoke on "The History of Medical Ethics." Dr. Walter L. Bierring, Des Moines, Ia., president of the fraternity, and Dr. Josiah J. Moore, Chicago, secretary, were the installing officers. President T. S. Painter of the University of Texas was made an honorary member and presided at the dinner.

Postgraduate Medical Assembly.—The International Post-Graduate Medical Assembly of Southwest Texas will be held in San Antonio at the Municipal Auditorium January 23-25, under the presidency of Dr. Merton M. Minter, San Antonio. Among the speakers will be:

Frank L. Meleney, New York, Intelligent Use of Antibacterial Agents.
Keith J. R. Wightman, Toronto, Canada, Clinical Disturbances of Fat Absorption.
C. Wilbur Rucker, Rochester, Minn., Lesions at the Optic Chiasm.
Hugh F. Hare, Boston, Effect of Radiation on Personnel.
Isador S. Ravdin, Philadelphia, Gallstone Disease.
Oscar Swinford Jr., Charlottesville, Va., ACTH and Cortisone in Allergic Diseases.
Mather Cleveland, New York, Intracapsular Fractures of the Neck of the Femur.
Alexander A. Weech, Cincinnati, Certain Aspects of Infant Feeding.
M. Ruiz Castaneda, México, D. F., Problems Concerning Epidemiology, Pathology and Pathogenesis of Brucellosis.
James H. Wall, White Plains, Psychoneurotic Conditions with Particular Emphasis on Obsessive and Compulsive States.
Walter B. Hoover, Boston, Dizziness from the Otolaryngological Standpoint.
William W. Scott, Baltimore, Geriatrics with Special Reference to Urological Problems.
Charles H. Slocumb, Rochester, Minn., Conditions in Which ACTH and Cortisone Are of Value.
Frank R. Lock, Winston-Salem, N. C., Management of Prolonged Labor.
William A. Meissner, Boston, Pathologic Observations on Thoracoplasty Failure in Tuberculosis.

The fee of $20 should be sent to International Post-Graduate Medical Assembly, P. O. Box 2445, San Antonio, Texas.

VIRGINIA

Narcotic Violations.—Dr. Ernest B. Nuckols, Cumberland, pleaded guilty to an indictment charging violation of the federal narcotic laws in the U. S. District Court at Lynchburg. On June 5 his sentence of one year and one day was suspended and he was placed on probation for a period of three years. He was also fined $10,000, which was to be paid within 60 days.

Dr. Marshall T. Garrett of Charlottesville pleaded guilty to an indictment charging violation of the federal narcotics laws in the U. S. District Court at Lynchburg. On June 5 his sentence of one year and one day was suspended and he was placed on probation for a period of three years. He was fined a sum of $2,500, which was to be paid within 60 days.

WISCONSIN

Marquette University Appointments.—Dr. William W. Engstrom, who has been associated with the Yale University School of Medicine since 1946, was one of three assistant professors named this fall to the staff of Marquette University School of Medicine, Milwaukee. Others appointed are Dr. John E. Steinhaus, department of pharmacology, and Dr. B. Wesley Catlin, former associate in research at Carnegie Institute, Long Island, N. Y. Dr. Michael W. Shutkin, attending physician at Mount Sinai Hospital, Milwaukee, has been made an assistant clinical professor of medicine. Four Milwaukee physicians have joined the Marquette staff as clinical instructors. They are Drs. Paul S. Pierson, Lloyd F. Jenk, Walton D. Thomas and E. Franklin Carl. Two Marquette medical faculty members were recently promoted to the rank of full clinical professors. They are Drs. Edward R. Krumbiegel, Milwaukee city health commissioner, Marquette Department of Public Health, and Gerhard D. Straus, department of otolaryngology.

GENERAL

Dr. Myers Named Dearholt Medalist.—Dr. J. Arthur Myers, Minneapolis, was named the recipient of the 1950 Dearholt Medal, given annually by the Mississippi Valley Conference on Tuberculosis for outstanding contributions to tuberculosis control. Dr. Myers is a past president of the National Tuberculosis Association, chief of the University of Minnesota Chest Clinic and a former member of the editorial board of the *American Review of Tuberculosis*, publication of the American Trudeau Society. He has written a history of antituberculosis work in Minnesota.

Plague Infection in Fleas.—According to the U. S. Public Health Service, in a report dated October 20, plague infection was proved positive in 17 fleas taken from two wood rats trapped April 22 about 17 miles east of Albuquerque in Bernalillo County, New Mexico. Under the same date the service reported that plague infection was proved positive in the following specimens taken two and a half miles west of Perico in Dallam County, Texas: 118 fleas from one prairie dog shot October 10 and 118 fleas flagged October 7 from prairie dog burrows.

Treatment Centers for Emotionally Disturbed Children.—A national survey of treatment centers that handle emotionally disturbed children will be made by the Child Welfare League of America under a grant of $26,000 from the Marshall Field Foundation. The purpose of the study is to analyze the best means of aiding emotionally disturbed children and preventing juvenile delinquency. The league will also provide consultation service to communties, social agencies and individuals interested in this work. Joseph Reid, assistant director of the league, will direct the survey.

Fraternity Fellowship Awarded.—Kappa Kappa Gamma, women's college fraternity, has awarded the $2,000 Harriet Ford Griswold Fellowship for study of rehabilitation in physical medicine to Dr. Yaeko Kawai, of Tokyo. The grant will provide transportation, lodging, food and incidental expense. New York University-Bellevue Medical Center, department of physical medicine and rehabilitation, will provide free tuition. The International Society for the Welfare of Cripples will administer the grant. Dr. Kawai was valedictorian of her class at Women's Medical College in Tokyo and since graduation has been engaged in research work at the biochemical laboratory of Nihon University.

Dr. Cook Honored.—Resolutions passed at the recent decennial meeting of the U. S. Pharmacopeial Convention were presented to E. Fullerton Cook, Pharm. D., Philadelphia, retired U. S. P. Revision chairman, at a luncheon on November 28. The luncheon was attended by most of the members of the board which served during the 1940-1950 decade as well as many of the present board. Dr. Cook was associated with the Pharmacopeia for 50 years. He served as assistant to the chairman of the U. S. P. Committee of Revision for almost 20 years and held the chairmanship from 1920 to 1950. His leadership helped make possible great contributions to the advancement of pharmacy, medicine, dentistry and other related sciences. The resolutions of the convention were presented to Dr. Cook in the form of an embossed and illuminated framed scroll.

Student Nurse Admissions Reach Five Year Record.—Schools of nursing throughout the United States admitted in 1950 the largest class in five years, according to the Committee on Careers in Nursing. A total of 44,185 first year students were admitted to the nearly 1,200 state-approved schools offering basic nursing programs, representing an increase of 1.3 per cent over admissions for the preceding year. The largest percentage increases were reported by Mississippi and Louisiana, 28 and 53 per cent, respectively. Although total admissions were up, 26 states showed fewer students admitted than in 1949, seventeen of these in the southern and far western sections of the country. Decreases of as much as or more than 15 per cent were reported in the District of Columbia, South Carolina, Montana, Arkansas and Arizona.

Society Elections.—At the annual meeting of the American Society for the Study of Arteriosclerosis in Chicago in November Dr. E. Cowles Andrus, Baltimore, was installed as president, and Dr. G. Lyman Duff, Montreal, was chosen vice president. Dr. Otakar J. Pollak, Quincy, Mass., was reelected secretary-treasurer.——At the recent meeting of the American Chemical Society Richard O. Roblin Jr., Ph.D., Stamford, Conn., was elected 1951 chairman of the Division of Medicinal Chemistry. Chester M. Suter, Ph.D., Rensselaer, N. Y., was elected vice chairman and Marcus G. Van Campen, Ph.D., Cincinnati, secretary-treasurer.——The Central Society for Clinical Research has elected the following officers to serve in 1951: Dr. William B. Bean, Iowa City, president; Dr. William B. Wood Jr., St. Louis, vice president, and Dr. Kenneth G. Kohlstaedt, Indianapolis, secretary-treasurer.

Surgeons Sectional Meetings.—The first of a series of seven sectional meetings of the American College of Surgeons will be held in St. Louis on January 22-23, with headquarters at the Hotel Statler. The other sectional meetings will be held in Hot Springs, Va., February 26-27; Philadelphia, March 5-6; New Haven, Conn., March 16-17; Portland, Ore., March 26-27; Denver, April 6-7, and Detroit, May 10-11. The medical profession at large and medical students are invited to the meetings. The St. Louis meeting, opening at 8:30 a. m. both mornings with medical motion pictures, will be followed at 10:00 a. m. by a scientific session on Surgery for Ischemic Diseases, Emergency Management of the Injured Chest, Fractures about the Ankle Joint, and Hematuria Following Trauma: Present Means of Diagnosis and Treatment. At a dinner the first evening Dr. Melvin A. Casberg, dean, St. Louis University School of Medicine, will speak on "The Medical Organization of the Chinese Communists." From 8:30 to 10:00 p. m. there will be a symposium on cancer. On the day following the sectional meeting in St. Louis, January 24, a full day of clinics will be held in St. Louis hospitals for the visiting surgeons.

WHO Sets Standards for 16 Biological Substances.—An international standard for pituitary adrenocorticotropic hormone (ACTH) has been established by the Expert Committee of the World Health Organization on Biological Standardization. Meeting in Geneva in November, the committee also set up international standards for 15 other biologic substances, including certain vitamins, hormones, antibiotics, serums and antitoxins. (Thirty-nine biologic preparations had already been standardized either by WHO or, previously, the Health Organization of the League of Nations.) International biologic standards are provided by WHO in order to enable research workers and manufacturers everywhere to have a single, internationally accepted measure for the activity of the substances which they produce. Among some of the most important standards established last week, were also those for anti-Rh, and anti-A and anti-B blood-grouping serums: lecithin and cardiolipin, tubocurarin, streptomycin and dihydrostreptomycin, aureomycin, terramycin and diphtheria toxoid. A standard was also set up for hyaluronidase. In addition, in order to facilitate research on antibiotics, the committee decided to recommend the establishment of an international collection of specimens of new antibiotics to be made available to scientists all over the world. The international collection of new antibiotics recommended by the Expert Committee would consist of preparations contributed by research workers and found to present clinical and research interest. It would be kept at the National Institute for Medical Research (London) for distribution on request to scientists anywhere in the world. The committee also reported progress in standardizing vaccines. Examination of samples suitable to serve as standards is being carried out on cholera, whooping cough and smallpox vaccines in various laboratories.

Courses in Use of Radioisotopes.—The eighteenth, nineteenth and twentieth courses in the technics of using radioisotopes in research will be given by the Special Training Division of the Oak Ridge Institute of Nuclear Studies during the winter and spring of 1951. Dates for the courses are January 8-February 2, February 19-March 16 and April 16-May 11. The courses consists of laboratory work, lectures on laboratory experiments, general background lectures and seminars on special topics. Experiments are conducted covering the use and calibration of instruments, the purification and separation of radioactive materials from inert and other radioactive materials, measurement and use of C^{11}, pile activations, radioautographs and the like. Seminars include the use of radioisotopes in animal experimentation, use of radioisotopes in humans, principles and practice of health physics, design of radiochemical laboratories and effect of radiation on cells. The Special Training Division can accommodate 32 participants at each of the three courses. A registration fee of $25 is charged, and participants will bear their own living and traveling expenses. A two week advanced course in radioisotopes will be given by the Oak Ridge Institute of Nuclear Studies beginning February 5. The course is intended for research workers in the field of medicine who have had experience in the basic technic of using radioisotopes. Lecturers from numerous hospitals using radioisotopes, Oak Ridge National Laboratory and staff members of the Medical and Special Training Division of the Institute will participate. The first week will be devoted to lectures and laboratory work on radioisotopes in therapy and the second with radioisotopes in clinical tracer studies. A limited number of applicants who are able to attend for only one week can be accommodated. A fee of $25 will be charged for the course. Applications are available from Dr. Ralph T. Overman, chairman, Special Training Division, Oak Ridge Institute of Nuclear Studies, P. O. Box 117, Oak Ridge.

CANADA

Eye Bacteriology Laboratory.—An eye bacteriology laboratory has been established by the Banting Institute in the Department of Ophthalmology, University of Toronto. The laboratory is under the direction of Dr. Hugh L. Ormsby. Ophthalmologists may refer their private patients to the laboratory for bacteriologic investigation.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: *Written.* July 20. Given simultaneously in several cities in the United States. Final date for filing application is Jan. 20. *Oral.* Coronado, Calif., April 4-7 and Memphis, Oct. 14-17. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Neurological Surgery: *Oral.* Chicago, May 1951. Sec., Dr. W. J. German, 789 Howard Ave., New Haven 4, Conn.

American Board of Obstetrics and Gynecology: Part I, Written Examination and Review of Case Histories. Various locations. Feb. 2, 1951. Final date for filing applications was Nov. 5. *Oral.* New York City, May 10-16. Final date for filing application is Feb. 2. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6, Pa.

American Board of Ophthalmology: *Written.* Various Centers, Jan. 5-6, 1951. *Oral.* San Francisco, March 11-15; New York, May 31-June 5; Chicago, October 8-13. Sec., Dr. Edwin B. Dunphy, 56 Ivie Road, Cape Cottage, Maine.

American Board of Orthopaedic Surgery: *Part II.* Chicago, Jan. 25-26. Final date for filing applications was Aug. 15, 1950. Final date for receipt of Part I applications for 1951 is Dec. 30, 1950. Sec., Dr. Harold A. Sofield, 122 So. Michigan Ave., Chicago 3.

American Board of Otolaryngology: *Written.* New York, Jan. 8-11, 1951. *Oral.* Richmond, Va., May 1-5. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City.

American Board of Pathology: *Written and Oral. Pathological Anatomy and Clinical Pathology.* Cleveland, April 23-24. Final date for filing application is March 15. Sec., Dr. Robert A. Moore, 1402 S. Grand Blvd., St. Louis.

American Board of Pediatrics: *Written.* Jan. 19. Under local monitors. Only written examination to be given during 1951. *Oral.* New Orleans, March 2-4. Ex. Sec., Dr. John McK. Mitchell, 6 Cushman Road, Rosemont, Pa.

American Board of Proctology: *Part I in Anorectal Surgery and Proctology.* Kansas City, Minneapolis, Philadelphia and San Francisco, May 12. Sec.-Gen., Dr. Louis A. Buie, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Psychiatry and Neurology: New York, Dec. 18-19. Final date for filing applications was Sept. 1. Sec., Dr. Francis J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: *Oral.* Atlantic City, June 5-9. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various centers, March 1951. Final date for filing applications was Dec. 1, 1950. *Written.* Various centers, Oct. 1951. Final date for filing applications is July 1. Sec., Dr. J. Stewart Rodman, 225 South 15th Street, Philadelphia.

Board of Thoracic Surgery: *Written.* Various Centers, Feb. 17. Final date for filing application is Feb. 1. *Oral.* New York City, April 19. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit.

American Board of Urology: Chicago, Feb. 10-14, 1951. Final date for filing applications was Sept. 1, 1950. Chicago, Feb. 9-13, 1952. Final date for filing applications is Sept. 1. Sec., Dr. Harry Culver, 314 Corn Exchange Bldg., Minneapolis 15.

Coming Medical Meetings

American Academy of Allergy, Hotel Statler, New York, Feb. 5-7. Dr. Walter S. Burrage, 208 E. Wisconsin Ave., Milkaukee 2, Secretary.

American Academy of Orthopaedic Surgeons, Palmer House, Chicago, Jan. 27-Feb. 1. Dr. Harold B. Boyd, 122 S. Michigan Ave., Chicago 3, Secretary.

American Society for Surgery of the Hand, Palmer House, Chicago, Jan. 26. Dr. Joseph H. Boyes, 1401 S. Hope St., Los Angeles 15, Secretary.

Atlanta Graduate Medical Assembly, Municipal Auditorium, Atlanta, Ga., Feb. 5-7. Mrs. Stewart R. Roberts, 768 Juniper St. N.E., Atlanta, Executive Secretary.

International Post-Graduate Medical Assembly of Southwest Texas, Municipal Auditorium, San Antonio, Jan. 23-25. Dr. John H. Hinchey, P. O. Box 2445, San Antonio 6, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 13-17. Dr. Victor J. Montilla, P. O. Box 3860, Santurce 29, Secretary.

DEATHS

Shurly, Burt Russell ⊕ Detroit; born in Chicago, July 4, 1871; Detroit College of Medicine, 1895; did postgraduate work at the University of Vienna; professor emeritus of otolaryngology at Wayne University College of Medicine, formerly known as the Detroit College of Medicine, which he joined in 1896, serving as instructor, lecturer in physiology, professor of otolaryngology and at one time dean; veteran of the Spanish-American War; for many years chief surgeon of the Michigan Naval Reserve; during World War I was in command of Base Hospital No. 36, American Expeditionary Forces stationed in Vittel, France, and was cited by General Pershing for his army service; later a colonel in the medical reserve corps; awarded the Purple Heart and the Legion of Honor; secretary of the Section on Laryngology, Otology and Rhinology from 1911-1913 and chairman 1913-1914 and from 1922 through 1948; member of the House of Delegates of the American Medical Association; past president of the American Laryngological Association, American Laryngological, Rhinological and Otological Society and the American Academy of Ophthalmology and Otolaryngology, which awarded him its gold medal; past president of the Detroit Academy of Medicine; fellow of the American College of Physicians and member of the American Climatological Association; fellow and formerly member of the board of governors of the American College of Surgeons; past president of the Detroit Chapter of the Association of Military Surgeons of the United States; past commander of the Detroit Chapter of Military Order of the World War; for many years member of the board of education, of which he had been president; a member of the board of directors and vice president of the American Board of Otolaryngology from 1930 to 1945; chief of staff, Shurly Hospital; president of Detroit Tuberculosis Sanitarium; consulting otolaryngologist at Woman's Hospital, Receiving Hospital and Harper Hospital, where he died October 20, aged 79, of coronary sclerosis and diabetes mellitus.

Brown, Percy ⊕ Egypt, Mass.; born in Cambridge, Nov. 24, 1875; Harvard Medical School, Boston, 1900; completed internship at Children's Hospital in Boston; in 1903 organized x-ray departments at the Children's Hospital and Carney Hospital in Boston and in 1904 inaugurated x-ray service at the Long Island Hospital and at St. Elizabeths' Hospital in Boston; in 1903 served as an assistant in the use of the roentgen ray at his alma mater; member of the American Roentgen Ray Society, of which, after serving in various official capacities, he became president in 1911 and in 1939 was awarded its president's medal; past president of the Radiological Society of North America, which in 1922 awarded him the gold medal for his research in roentgen diagnosis and therapy; fellow of the American College of Physicians and the American College of Radiology; member of the New York Roentgen Society, Philadelphia Roentgen Ray Society, New England Roentgen Ray Society, the original Roentgen Society of London and before World War I the Deutsche Roentgen Gesselleschaft of Berlin; served during World War I as a major in the medical corps, U. S. Army, with Base Hospital No. 5 in France; specialist certified by the American Board of Radiology; variously associated, as radiologist, with the Jackson Clinic, Madison, Wis., the Grunow Clinic of Phoenix, Ariz., the Western Pennsylvania Hospital of Pittsburgh and St. Luke's Hospital in New York; author of a monograph (1935) on "American Martyrs to Science Through Roentgen Rays"; died October 8, aged 74, of hypertensive heart disease.

Cottis, George W., Jamestown, N. Y.; born in Guelph, Canada, March 18, 1880; Cornell University Medical College, New York, 1904; specialist certified by the American Board of Surgery; past president of the Medical Society of the State of New York; past president of the Jamestown and Chautauqua County Medical societies; fellow of the American College of Surgeons; a captain overseas in the Royal Army Medical Corps during World War I; in 1928 member of the House of Delegates of the American Medical Association; served on the staffs of Jamestown General and Woman's Christian Association hospitals; formerly chairman of the New York State governor's committee on public health and of the board of visitors of the State Institute for the Study of Malignant Diseases in Buffalo; associate editor of the *New York State Journal of Medicine* from November 1944 to December 1945; past president of the local Chamber of Commerce; died in St. Cloud, Fla., October 19, aged 70, of coronary occlusion.

Brunn, Harold ⊕ San Francisco; born in San Bernardino, Calif., in 1874; University of Pennsylvania Department of Medicine, Philadelphia, 1895; an Associate Fellow of the American Medical Association; member of the founders group of the American Board of Surgery; clinical professor of surgery, emeritus, at the University of California Medical School in San Francisco; chairman of the Section on Surgery, General and Abdominal, American Medical Association, 1933-1934; member of the American Surgical Association, Pacific Coast Surgical Association and the American Association for Thoracic Surgery, of which he had been a past president; fellow of the American College of Surgeons; established the Harold Brunn Cardio-Vascular Research Institute; served as surgeon in chief at San Francisco Hospital, University of California Service and was chief of surgical service at Mount Zion Hospital; in 1942 50 pupils and friends dedicated a book to him; died October 5, aged 76.

Levenson, Walter Sabin ⊕ Boston; Harvard Medical School, Boston, 1922; specialist certified by the American Board of Surgery; president of the Greater Boston Medical Society; member of the New England Pediatric Society; fellow of the American College of Surgeons; during World War II served as a commander in the U. S. Navy Reserve and was decorated with the Navy Bronze Medal for service in the Philippine invasion; instructor in surgery, Tufts College Medical School and assistant in surgery at Harvard Medical School; on the staffs of the Beth Israel Hospital, Boston Dispensary and Boston Floating Hospital; died in New York University Hospital in New York September 22, aged 52, of carcinoma of the liver.

Dye, William Joseph Paul ⊕ Wolfeboro, N. H.; born in Sistersville, W. Va., Nov. 10, 1902; Harvard Medical School, Boston, 1925; secretary of the Carroll County Medical Society; vice president of the New Hampshire Medical Society; secretary-treasurer of the New Hampshire Surgical Club; certified by the National Board of Medical Examiners; specialist certified by the American Board of Surgery; member of the New England Obstetrical and Gynecological Society and the New England Surgical Society; chairman of the state board of registration in medicine; on the staff of Huggins Hospital, where he died October 17, aged 47, of coronary thrombosis.

Getchell, Albert Colby, Worcester, Mass.; born in Waterville, Maine, July 9, 1857; Jefferson Medical College of Philadelphia, 1885; member of the American Medical Association; for many years president of the Worcester Tuberculosis Relief Association; fellow of the American College of Surgeons; served on the staffs of Belmont, Memorial and Worcester City hospitals; consulting laryngologist and trustee, Rutland, (Mass.) State Sanatorium; consulting physician, Hospital Cottages for Children in Baldwinsville; organized the Worcester District Medical Library, serving as its librarian for many years; died in Princeton October 1, aged 93, of senility.

Kidner, Frederick Clinton ⊕ Detroit; born in Ipswich, Mass., April 13, 1879; Harvard Medical School, Boston, 1904; emeritus professor of clinical orthopedic surgery at Wayne University College of Medicine; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopedic Association, of which he had been president, Clinical Orthopedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; affiliated with Children's Hospital of Michigan, Woman's Hospital, Receiving Hospital and Harper Hospital, where he died October 20, aged 71.

Bosworth, Boardman Marsh ⊕ Bronxville, N. Y.; born in New York June 7, 1898; Columbia University College of Physicians and Surgeons, New York, 1931; specialist certified by the American Board of Surgery; certified by the National Board of Medical Examiners; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served during World War II; affiliated with Lawrence Hospital in Bronxville, Grasslands Hospital in Valhalla, Mount Vernon (N. Y.) Hospital and New York City Hospital; killed near Hainesville, N. J., October 9, aged 52, in a private airplane crash.

Lynch, Charles Francis ⊕ Springfield, Mass.; born in Waltham, Mass., in 1871; New York University Medical College, New York, 1897; an Associate Fellow of the American Medical Association; fellow of the American College of Surgeons; served overseas during World War I; at one time member of the state public health council; formerly chairman

---

⊕ Indicates Fellow of the American Medical Association.

of the police commission; senior surgeon, Mercy Hospital; consulting surgeon, Health Department Hospital in Springfield, Wing Memorial Hospital in Palmer and Amherst College Infirmary in Amherst; died in Mercy Hospital September 27, aged 79, of coronary thrombosis.

Lee, Thomas Benjamin ⊕ Collingswood, N. J.; born in 1881; Jefferson Medical College of Philadelphia, 1905; past president of the Camden County Medical Society and the New Jersey State Department of Health; formerly trustee of the New Jersey State Medical Society; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; consulting gynecologist, Zurbrugg Memorial Hospital, Riverside, Salem County Memorial Hospital, Salem, Underwood Hospital, Woodbury and the Cooper Hospital in Camden, where he died October 17, aged 69.

Parowski, Stephen Anthony ⊕ Assistant Surgeon Lieutenant (jg) U. S. Navy, retired, San Diego, Calif.; born in Chicago Aug. 31, 1899; Rush Medical College, Chicago, 1927; served during World War I; entered the U. S. Navy June 30, 1925; retired March 31, 1928 for incapacity resulting from an incident of the service; fellow and past president of the American College of Chest Physicians; member of the American Trudeau Society; on the staffs of Mercy, Quintard and Balboa hospitals and Rest Haven Preventorium; died October 7, aged 51.

Alguire, Annie Bell McCallum ⊕ Belvidere, Ill.; Trinity Medical College, Toronto, Canada, 1895; formerly member of the county school board; affiliated with Highland and St. Joseph's hospitals; died October 8, aged 82, of hypertension and cerebral hemorrhage.

Andres, Francis Anthony ⊕ Allegany, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1931; served during World War II; physician at St. Bonaventure's (N. Y.) College; on the staffs of Olean General Hospital and St. Francis Hospital in Olean, where he died October 21, aged 46, of coronary insufficiency.

Aptaker, Albert J., ⊕ Forest Hills, N. Y.; University of Maryland School of Medicine, Baltimore, 1927; associate attending physician on the medical staff of Queens General Hospital in Jamaica; died October 19, aged 47, of coronary occlusion.

Benson, Otis Otto Sr., Minneapolis; Keokuk (Ia.) Medical College, 1898; Rush Medical College, Chicago, 1902; formerly associated with the Indian Service; died October 16, aged 83, of uremia.

Brisbine, Royal Ellis ⊕ Burbank, Calif.; State University of Iowa College of Medicine, Iowa City, 1906; affiliated with Behrens Memorial Hospital and Glendale Sanitarium and Hospital, where he died September 30, aged 70, of coronary occlusion.

Brown, Edwin Martin, Washington, N. C.; Bellevue Hospital Medical College, New York, 1896; member of the American Medical Association; past president of the Beaufort County Medical Society; received a citation for service rendered as examiner for the county selective board in World Wars I and II; served as county health officer; affiliated with Fowle Memorial Hospital; died September 28, aged 77, of coronary thrombosis.

Buchanan, John Roosevelt ⊕ Youngstown, Ohio; State University of Iowa College of Medicine, Iowa City, 1925; member of the American Academy of Orthopaedic Surgeons; specialist certified by the American Board of Orthopaedic Surgery; served during World War II; on the staff of Youngstown Hospital; died October 19, aged 49, of carcinoma of the pancreas.

Budau, John Harry Diederichs, Milford, Conn.; Yale University School of Medicine, New Haven, 1900; member of the American Medical Association; died in Bridgeport August 21, aged 75, of rupture of an abdominal arteriosclerotic aneurysm.

Burt, Lawrence William, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1936; member of the American Medical Association; served during World War II; affiliated with Touro Infirmary; died September 29, aged 40.

Ciolli, Dominic Trinity ⊕ Buffalo; University of Buffalo School of Medicine, 1920; member of the American Psychiatric Association; affiliated with Edward J. Meyer Memorial, Deaconess, Sisters of Charity and Buffalo Columbus hospitals; died in the township of Holland, N. Y., October 22, aged 55, of coronary disease.

Clendenen, Charles M., Damascus, Va.; University College of Medicine, Richmond, 1910; president of the Bank of Damascus; died in the George Ben Johnston Hospital, Abingdon, September 29, aged 66, of congestive heart failure.

Cogswell, John Wilkinson, Strasburg, Ohio; State University of Iowa College of Homeopathic Medicine, Iowa City, 1906; member of the American Medical Association; served during World War I; on the associate staff of the Massillon (Ohio) Hospital and Union Hospital in Dover, where he died October 9, aged 67, of heart disease.

Crossland, John R. A., St. Joseph, Mo.; Meharry Medical College, Nashville, Tenn., 1890; died in State Hospital No. 2, September 13, aged 86.

Cush, Thomas James ⊕ Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1924; fellow of the American College of Surgeons; president of the Cambria County Medical Society; chief of orthopedic surgery at Mercy Hospital; a member of the reserve staff of the Conemaugh Valley Memorial Hospital, where he died September 30, aged 49, of coronary occlusion.

Davis, Albert Wellington ⊕ Kansas City, Mo., Kansas City Medical College, 1902; formerly on the staff of St. Luke's Hospital, where he died October 4, aged 87, of complications following a fractured hip received in a fall.

de la Pila Iglesias, Manuel, Ponce, P. R.; Universidad de Barcelona Facultad de Medicina, Spain, 1906; past president of the Porto Rico Medical Association; fellow of the American College of Physicians; member of House of Delegates of the American Medical Association in 1940, 1941, 1946 and 1947; medical director of the Clinica Quirurgica Dr. Pila; killed October 7, aged 66, in an automobile accident.

Dodge, Charles Harwood, Clinton, Wis.; Marquette University School of Medicine, Milwaukee, 1913; served in France during World War I; health officer of Clinton township; formerly member of the school board; died in Wisconsin General Hospital, Madison, September 8, aged 59, of coronary thrombosis.

Dryfuss, Barney Joachim ⊕ New York; University of Louisville (Ky.) Medical Department, 1903; Cornell University Medical College, 1905; formerly on the faculty of Cornell University Medical College; on the staff of St. Clare's Hospital, where he died October 14, aged 71, of dissecting aneurysm.

Duncan, Oscar Allen, Fort Leavenworth, Kan.; St. Louis University School of Medicine, 1905; civilian physician for the Army at Fort Leavenworth; died in the U. S. Army Hospital October 3, aged 70, of progressive muscular atrophy.

Dunkley, David A., Roanoke, Va.; University College of Medicine, Richmond, 1910; member of the American Medical Association; affiliated with Shenandoah Hospital, where he died September 26, aged 67, of thrombophlebitis with multiple pulmonary emboli.

Dunlay, Emmett Blaine, Watertown, N. Y.; University of Buffalo School of Medicine, 1920; member of the American Medical Association; served as medical school inspector for the public school system in Watertown; formerly on the staffs of the House of the Good Samaritan and Mercy Hospital; died recently, aged 57.

Evans, Evan Albert, Rosedale, Ind.; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; affiliated with Vermillion County Hospital in Clinton; died in St. Anthony's Hospital, Terre Haute, October 16, aged 71, of cerebral hemorrhage and hypertension.

Felberbaum, David ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1906; affiliated with Montefiore and Mount Sinai hospitals; died October 26, aged 67, of cerebral thrombosis.

Fitch, Josiah Whitaker, Louisville, Ky.; University of Louisville Medical Department, 1907; member of the American Medical Association; died in Jewish Hospital, September 22, aged 70, of gastric ulcer.

Fitch, Stewart Jackson, Laguna Beach, Calif.; the Hahnemann Medical College and Hospital, Chicago, 1914; served during World War I; died September 26, aged 65, of arteriosclerosis and edema of brain.

Fledderjohann, Henry E., New Knoxville, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1886; died in Dayton October 2, aged 94, of chronic myocarditis.

Fraser, Stuart Evans, North Miami, Fla.; the Hahnemann Medical College and Hospital, Chicago, 1917; died in Duke Hospital, Durham, N. C., October 5, aged 64, of arteriosclerosis with gangrene of both legs.

Gabel, William Jacob, Syracuse, N. Y.; Syracuse University College of Medicine, 1916; served on the staff of the Hospital of the Good Shepherd, where he died October 15, aged 60, of cardiac decompensation.

Gaines, Frank McFarland, Carrollton, Ky.; Kentucky School of Medicine, Louisville, 1893; formerly associated with the U. S. Public Health Service Reserve and was on the staffs of various Veterans Administration hospitals; served during World War I; died October 5, aged 80, of coronary occlusion.

Garman, Russell Arthur ⊕ Jeannette, Pa.; Jefferson Medical College of Philadelphia, 1930; past president of the Westmoreland County Medical Society; served during World War II; was shot and killed by a former patient October 1, aged 46.

Gershenson, Edward Harry, New York; Long Island College Hospital, Brooklyn, 1905; died in Beekman Hospital October 5, aged 68, of cerebral accident.

Goldsmith, Leon Albert ⊕ Portland, Ore.; Harvard Medical School, Boston, 1922; assistant clinical professor of cardiology at the University of Oregon Medical School; specialist certified by the American Board of Internal Medicine; member of the North Pacific Society of Internal Medicine; fellow of the American College of Physicians; affiliated with Multnomah Hospital; died in Chicago November 2, aged 53, of coronary heart disease.

Grace, James Joseph, Springfield, Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1933; member of the American Medical Association; school physician; served in the Pacific area during World War II; affiliated with Mercy Hospital; died October 17, aged 44, of carcinoma of the rectum.

Griffith, Guy Everett ⊕ Tacoma, Wash.; Northwestern University Medical School, Chicago, 1920; died in Santa Monica, Calif., October 13, aged 61, of cerebral vascular accident and coronary occlusion.

Grover, Joseph Isaac ⊕ Quincy, Mass.; Harvard Medical School, Boston, 1911; an Associate Fellow of the American Medical Association; affiliated with Quincy City Hospital; died October 19, aged 65, of carcinoma of the duodenum.

Hapeman, Harry, Minden, Neb.; Rush Medical College, Chicago, 1882; fellow of the American College of Surgeons; died October 29, aged 92, of uremia.

Harrison, William H., Kokomo, Ind.; Medical College of Indiana, Indianapolis, 1896; member of the American Medical Association; past president of the Howard County Medical Society; died October 23, aged 85, of cerebral hemorrhage and arteriosclerosis.

Hazlett, Almon Cyrus ⊕ Wyoming, Pa.; Jefferson Medical College of Philadelphia, 1913; served with the American Expeditionary Forces overseas during World War I; past president of the Luzerne County Medical Society; affiliated with Nesbitt Memorial Hospital in Kingston and Pittston (Pa.) Hospital; died in Philadelphia October 17, aged 59, of ruptured aneurysm of the circle of Willis.

Hogan, Stephen Clement ⊕ Chicago; Chicago College of Medicine and Surgery, 1912; died October 31, aged 67, of cerebral hemorrhage and hypertensive heart disease.

Jacobs, Francis Edward ⊕ San Diego, Calif.; University of Oregon Medical School, Portland, 1929; past president of the San Diego County Medical Society; served on the staffs of San Diego County and Quintard hospitals; died in Woodland Clinic Hospital, Woodland, October 14, aged 47, of coronary occlusion.

Kenkel, Henry Frank, Cincinnati; University of Cincinnati College of Medicine, 1920; died October 19, aged 56, of acute coronary occlusion.

Koempel, Franz, New York; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1893; died October 31, aged 80.

Lasher, Earl Parsons, Newtown, Conn.; Albany (N. Y.) Medical College, 1898; formerly affiliated with the New York Eye and Ear Infirmary in New York; died in the Danbury (Conn.) General Hospital October 28, aged 77, of cerebral hemorrhage and pulmonary embolism.

Liles, Homer D., Flowery Branch, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913; served during World War I; died in Hall County Memorial Hospital, Gainesville, October 20, aged 61, of cardiac asthma.

Mack, Gertrude Griswold, New York; New York Medical College and Hospital for Women, Homeopathic, New York, 1897; died recently, aged 77, of coronary thrombosis.

McCord, James Bennett, Oakham, Mass.; Northwestern University Medical School, Chicago, 1894; for many years medical missionary of the American Board of Foreign Missions in Africa and founder of the McCord Zulu Hospital, the first hospital for Africans in Natal Province; died October 5, aged 80, of heart disease.

McCoy, Earl Tucker, Los Angeles; College of Physicians and Surgeons, Los Angeles, 1918; member of the American Medical Association; formerly on the staff of the Methodist Hospital of Southern California; died September 14, aged 65, of coronary thrombosis.

McMahan, Asher Reid, Memphis, Tenn.; Rush Medical College, Chicago, 1908; member of the American Medical Association; served on the staffs of Gartly-Ramsay, Baptist, St. Joseph and Methodist hospitals; medical director of the Columbian Mutual Life Insurance Company; died in Baptist Hospital October 17, aged 67, of carcinoma of the prostate.

Macon, Gideon Hunt, Warrenton, N. C.; University College of Medicine, Richmond, 1910; member of the American Medical Association; served as vice president of the Medical Society of the State of North Carolina; died in Park View Hospital, Rocky Mount, October 1, aged 63, of coronary occlusion.

Meck, Henry Lehr, Dundee, Mich.; Detroit College of Medicine, 1910; member of the American Medical Association; served during World War I; on the staff of Mercy Hospital, Monroe; for many years president of the Monroe County Bank; died in Ontario, Canada, October 4, aged 65, of heart disease.

Mullins, Charles Ellison ⊕ Meadville, Miss.; Memphis (Tenn.) Hospital Medical College, 1909; served as vice president of the Mississippi State Medical Association; county health officer; died in King's Daughters Hospital, Brookhaven, September 22, aged 66, of acute cardiac failure.

Munn, Jesse Adolphas ⊕ McAlester, Okla.; University of Arkansas School of Medicine, Little Rock, 1910; served during World War I; associated with St. Mary's and Albert Pike hospitals; died August 27, aged 67, of coronary embolism.

Resnisky, Andrew Francis, Hartford, Conn.; Georgetown University School of Medicine, Washington, D. C., 1923; fellow of the American College of Surgeons; on the staff of St. Francis Hospital; died in Windham Memorial Hospital in Willimantic, September 28, aged 52, of coronary thrombosis.

Rogers, James Coburn, Bellefonte, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1905; school physician; on the staff of Centre County Hospital; died in Philipsburg (Pa.) State Hospital September 29, aged 66, of arteriosclerotic heart disease.

Schoolman, Noah, Chicago; Jefferson Medical College of Philadelphia, 1903; formerly associated with the Illinois Charitable Eye and Ear Infirmary; died October 21, aged 75, of arteriosclerotic heart disease.

Siefert, John Frederick, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; died October 13, aged 88, of bronchopneumonia and cerebral thrombosis.

Taylor, Emora Arthur, Gulfport, Miss.; Leonard Medical School, Medical Department Shaw University, Raleigh, N. C., 1906; affiliated with Memorial Hospital; died September 13, aged 70, of cerebral hemorrhage and arteriosclerosis.

Twitchell, Edward Woodland, San Francisco; Cooper Medical College, San Francisco, 1892; specialist certified by the American Board of Psychiatry and Neurology; member of the American Medical Association; clinical professor of psychiatry emeritus at University of California Medical School; died September 2, aged 78, of cerebral hemorrhage.

Valentine, Clarence Medbery ⊕ Columbus, Ohio; Starling Ohio Medical College, Columbus, 1908; served during World War I; first health commissioner of Franklin County; affiliated with Mercy Hospital, St. Ann's Maternity Hospital and the Grant Hospital, where he died October 2, aged 67, of coronary thrombosis.

Wallace, George Sellers, Hilliard, Fla.; Jefferson Medical College of Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania and the American Medical Association; died in Lake City, September 26, aged 81, of carcinoma of the prostate.

Weber, Burghard Andrew, Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1898; died in Milwaukee County Hospital August 26, aged 76, of coronary thrombosis and diabetes mellitus.

Trend in Modern Surgery

Recently the London *Times* reported a speech given by Sir Cecil Wakeley, president of the Royal College of Surgeons, London, when he gave the inaugural address to the Westminster Medical School at Church House, Westminster, London. He said that there seemed to be a tendency for teachers to specialize in a small aspect of surgery and beat it until it was dead and to take teaching away from those who were practicing surgery as a full time occupation. The latter, he said, were the very persons who were continually in touch with patients and their diseases and, therefore, were perhaps better able to teach, because of their more practical and less academic knowledge. He said there was a danger of ultraspecialization, when men would perform only one type of operation. Such a state of affairs was bad for teaching and made for little progress. It was important that teaching hospital surgeons should remain general surgeons, but, on the other hand, it did not matter if they had a specialty, for instance, gastric surgery, thyroid surgery or urological surgery.

There was also a tendency for some workers to overlook clinical observation and to rely too much on roentgenograms and pathological or biochemical tests in making a diagnosis. He doubted whether the clinician of today had the clinical acumen of the late Victorian physicians, who used few tests and in many instances were extraordinarily accurate in their diagnosis. He mentioned the new Medical Act and hoped that when it came into force, making a year's postgraduate experience compulsory before registration, the qualified student would be able to take part of his year's postgraduate training with a general practitioner. Surgery had by no means arrived at its zenith, and further progress was not impossible, although it might well be that future research would eliminate some forms of surgical operations and that some disease which had been treated by surgical intervention would be cured by intravenously administered drugs. Sir Cecil Wakeley, who presented the prizes, was welcomed by Mr. H. M. Clowes, chairman of Westminster Medical School.

Smoking and Carcinoma of the Lung

A preliminary report on smoking and carcinoma of the lung, by Drs. Richard Doll and A. Bradford Hill, appeared in the December 9 issue of the *British Medical Journal*. It states that the great increase in the number of deaths attributed to cancer of the lung in the last 25 years justifies the search for a cause in the environment. The authors investigated the possible association of carcinoma of the lung with such factors as smoking, exposure to car and fuel fumes and occupation.

The material for the investigation was obtained from 20 hospitals in London. Social workers visited and interviewed each patient. Patients with stomach or large bowel carcinoma and a noncancer control group, comparable in age and sex with the patients with lung cancer, served for comparison. A group of 649 men and 60 women with carcinoma of the lung were interviewed. Three-tenths per cent of the men and 31.7 per cent of the women were nonsmokers. The corresponding figures in the noncancer control groups were 4.2 per cent for the men and 53.3 per cent for the women. Twenty-six per cent of the male and 14.6 per cent of the female patients with lung cancer smoked the equivalent of 25 or more cigarets a day prior to their illness, while only 13.5 per cent of the male and none of the female noncancer control patients smoked as much. Similar differences were found when comparisons were made between the maximum amounts ever smoked and the estimated total amounts ever smoked. Cigaret smoking was more closely related to carcinoma of the lung than pipe smoking. No distinct association was found with inhaling. Taken as a whole, the patients with lung cancer had begun to smoke earlier and had continued for longer periods than the controls; the differences, however, were not statistically significant. Rather fewer patients with lung cancer had given up smoking.

The possibility of unreliable results was considered—those that could be due to the selection of an unsuitable group of control patients, or patients having respiratory disease exaggerating their smoking habits, or bias on the part of the interviewers. Care was taken to eliminate all these fallacies.

From consideration of smoking histories of patients without cancer of the lung, a tentative estimate was made of the number of persons who smoked different amounts of tobacco in Greater London, and the relative risks of development of the disease among different grades of smokers were calculated. Speculative figures only were obtained, and it is suggested that above the age of 45 the risk of having the disease increases in simple proportion with the amount smoked, and it may be 50 times as great among those who smoke 25 or more cigarets a day as among nonsmokers. The authors observed sex ratio among nonsmokers (based, it must be stressed, on very few cases), saying the ratio can be readily accounted for if the true incidence among nonsmokers is equal in both sexes. It is not possible to deduce a simple time relation between the increased consumption of tobacco and the increased number of deaths attributed to cancer of the lung. It may possibly be due to improved diagnosis, and it may be because the carcinogen in tobacco smoke is introduced into the tobacco during its cultivation or preparation. Greater changes have taken place in the methods involved in these processes than in the actual amount of tobacco consumed.

Disordered Society

During his work in an international organization for the care of refugees R. N. Tronchin-James observed interesting patterns of human behavior in the insecure and disordered world of today. The refugee is the physical example of the insecurity that may overtake anyone. Observations made over 18 months on a refugee population of 30,000 in Austria are recorded. Although the population under consideration consisted of persons of every age group and many nationalities, various creeds and different professional, social and economic status, their situation reduced them to a common plight, with similar mental reactions.

The symptoms of more typical reactive or conversion neurosis were not found in this large population. A form of neurosis widespread among the refugees was characterized by emotional shock persisting for years, with suppression of active and aggressive psychic qualities, lack of volition and emotional incapacity to consider the future. There was a positive resistance to change, even though the present was more insecure, uncomfortable and completely different from the previous pattern of life. The physical care was good, and the physical necessity of transporting them to new countries was dealt with energetically and with considerable success.

When such situations are imminent, workers should attempt to restore the refugees to mental health, so that each regains the fullest vigor of his ethnic and individual capacities for dealing with the new situation and environment that he has to face. The capacity for adjustment to a new situation is a criterion of his mental health. To restore to the refugee the fullest enjoyment of that capacity should be the primary aim and, would decrease enormously the amount of purely supportive work that has to be done.

TURKEY

ANKARA, Oct. 28, 1950.

Eleventh National Medical Congress

This congress was held at Ankara Oct. 16-19, 1950, under the auspices of Celal Bayar, president of Turkey, and with Adnan Menderes, the prime minister, as honorary president. It was attended by almost 700 members from all parts of the country. Dr. Ekrem Hayri Üstündag, minister of health and social assistance, opened the congress. The topic was tuberculosis.

Ord. Prof. Tevfik Saglam of Istanbul University, Turkey's foremost authority on tuberculosis, spoke on tuberculosis control in Turkey; Dr. Tevfik Ismail Gökee, chief of the Istanbul Heybeliada Tuberculosis Sanatorium, on the positive results of antibiotic therapy; Dr. Etienne Berthet, consultant of tuberculosis for the World Health Organization, rehabilitation, reeducation and the medicosocial aspects of tuberculosis; Dr. Ihsan Rifat Sabar, tuberculosis control in other countries; Prof. Nusret Karasu, the source of tuberculosis infection and its effects and on the result of BCG vaccination of primary school children in Ankara; Dr. Ahmed F. Erbelger, cavernostomy, tamponade and extrapleural pneumothorax; Dr. Sacit Tezelli, the result of extrapleural collapse therapy in pulmonary tuberculosis; Dr. Turgut Targay, the role of pneumoperitoneum in the treatment of tuberculosis; Dr. Yakup Çelebi, chief of the Istanbul-Haydar Pasha Tuberculosis Hospital, the epidemiology of tuberculosis; Dr. Nureddin Onur, the results of BCG vaccination in Istanbul; Dr. Sebib Say, the result of BCG vaccination in infants, preschool and school children in Izmir; Ord. Prof. Mazhar Osman Uzman and Prof. Ihsan Sukri Aksel, psychological symptoms in the course of tuberculosis meningitis; Dr. (V.M.D.) R. Üner and Dr. (V.M.D.) F. Turker, tuberculosis in stray cats; Ord. Prof. Akif S. Shakar, streptomycin therapy in bone and joint tuberculosis; Dr. F. Dikengil, confirmation of bronchial destruction in tuberculous lymphadenopathy by postmortem bronchography; Prof. Nusret Karasu, the army and tuberculosis; Dr. Hasan Fehmi Gökalp, occupational therapy for the tuberculous; Prof. Rasim Adasal, dementia precox and the etiological relation to tuberculosis; Dr. Baha Arkan, school hygiene and tuberculosis; Prof. K. Mutlu, ten years' research on tuberculosis specimens in the pathological anatomy laboratory; Dr. Neşati Üster, tuberculosis in Bursa City and epidemiology; Dr. Orhan Zihni Sanus, increase of tuberculosis in Turkey in relation to standards of living; Prof. N. Karasu, Dr. N. Menemenli and Dr. M. Özköse, glucoregulation in tuberculosis; Dr. Ö. Bican, surgery in pulmonary tuberculosis; Dr. S. Berkman, mass chest examination; Dr. T. Gökce and Dr. S. Velicangil, investigation of bovine type tuberculosis in Turkey; Dr. I. Gürevin, spontaneous hypochloremia and hypochloremic nephropathy in tuberculosis; Dr. N. Tuna, changes in blood circulation in collapse therapy; Dr. A. L. Karan, skin tuberculosis and the skin in tuberculosis; Dr. R. T. Kinacigil, vitamin D_2 therapy in skin tuberculosis, and Prof. Karasu, Dr. Baloglu and Dr. Dülgeroglu, tuberculosis and adrenal function. Forty-three other communications were presented. This congress was accompanied with an exhibit of domestic and foreign pharmaceutical preparations and public health propaganda. After the congress, the health exhibit was open to the public.

At the United States Information Service Library at Ankara an opportunity was provided for the inspection of medical and medicosocial publications. Congress members were presented with a copy of "Books on Science," published by the United States Department of State. The next medical congress is to be held in 1952 at Ankara; the topic will be rheumatism.

Influenza Epidemic

With intermittent local epidemics, widespread epidemics of influenza occur in Turkey about every five years. The last epidemic outbreak in almost all the 63 provinces occurred in January 1949. Starting abruptly in Ankara, it continued for four weeks and subsided suddenly. The incidence was highest in Ankara (25 to 80 per cent); the mortality rate there was comparatively low. There were 126 deaths in the first week, of which 32 were caused by bronchopneumonic complications, 161 deaths in the second week, of which 53 were caused by bronchopneumonic complications, and 127 deaths in the third week, of which 46 were caused by bronchopneumonic complications.

According to investigations by Dr. Sabahaddin Payzin, director of the control laboratory at the Ankara Refik Saydam Institute of Hygiene, and Dr. Sadik Okkan, the serums of all patients had reacted positively to A antigen. A number of cases of highly toxic conditions with such complications as albuminuria, hilar lymphadenia and encephalomeningitis were observed.

Five groups of four mice each were given a nasal inoculation with a throat secretion from five patients. After three days a strain was cultivated. The dried lungs of the mice were crushed in a sterile mortar with sterile sand and penicillin, streptomycin and 5 cc. of sodium chloride solution added. Four other mice were inoculated with this suspension. The second passage caused several deaths. Samples of the fifth strain were sent for control to the World Influenza Central Institute, where Prof. Andrews identified them as an unknown subtype. Inoculations of squirrels also proved the virulence of the virus.

The virus of the Ankara epidemic was not the same as that of the French and Italian epidemics that occurred two months earlier. The Italian virus was the B type; the French type A virus was not exactly like the Ankara virus. The influenza virus type of surrounding countries not having been announced, the virulence of the Ankara endemic virus was possibly the result of mutation. Inoculation of the Refik Saydam Institute of Hygiene personnel with vaccine from the Eli Lilly laboratory proved effective. The following year there was no influenza epidemic in Turkey.

Fourth Turkish Microbiology Congress

Under the presidency of Dr. Ekrem Hayri Üstündag the congress was held on October 18-19 at Ankara. Dr. Nureddin Onur, chief of the Istanbul Hygiene Laboratory, spoke on the results of BCG vaccination in Istanbul; Dr. Sebib Say, on the results of BCG vaccination in Smyrne; Dr. (V.M.D.) Turgud Argun, tuberculosis epidemiology of cows in Turkey; Ord. Prof. Ihsan Hilmi Alantar and his associate Dr. Sezai Bedreddin Tümay of Istanbul University, clinical aspects of toxicosis and therapy and prevention of diarrhea in infants; Dr. N. Fakaçelli of Istanbul, parenteral treatment of infant diarrhea; Dr. Zekai Muammer Tuncman, Istanbul, epidemiology of rabies and precautionary measures in Turkey; Prof. Ihsan Shukrü Aksel of Istanbul University, encephalomeningitis after rabies vaccination, and Ord. Prof. (V.M.D.) Sureyya Aygün, control of rabies in animals. The next congress is to be held in 1952 at Ankara; the topics will be epidemiology and etiology of Q fever, poliomyelitis and tetanus. The seventh National Surgical Congress was held also on October 18; the most important subject was bone tuberculosis, with emphasis on the therapy of tuberculosis of the vertebrae, on which Prof. Hayri Nishantash reported.

Professor Nihad Reshad Belger

The minister of health and social assistance has resigned because of poor health. His successor is Dr. Ekrem Hayri Üstündag. He studied hygiene and bacteriology in Germany for five years and has for many years been active in public health work. He taught at the medical school in Damascus before World War I.

ITALY

(From a Regular Correspondent)

FLORENCE, Sept. 20, 1950.

Natural and Artificial Iodoproteins

Continuing the series of lectures on protein held at the Superior Institute of Public Health, Prof. Jean Roche of the Collège de France discussed natural and artificial iodoproteins. He said that the principal problems of iodine biochemistry in animals are linked to the presence of this element in some proteins, among which are three iodoamino acids, derived from L-thyroxine: 3-monoiodinethyroxine, 3-5-diiodinethyroxine and thyroxine. These substances are formed by halogenation of thyroglobulin in the thyroid of vertebrates and that of scleroprotein in the horny skeleton of invertebrates. The same result may be obtained with artificial halogenation, the biologic activity of the natural and of the artificial iodoproteins being qualitatively identical, except for some differences especially concerning the galactogenous power. Knowledge of the physiological property of the various iodoproteins is of importance for their application in medicine and zootechnics. With a brief survey of the composition and property of thyroglobulin the speaker pointed out that the thyroid effects, in the first stage, the synthesis of these proteins by incorporating tyrosine and, in the second stage, the halogens. Proteidogenesis and iodization are two successive, independent processes; the latter contributes to the formation of thyroxine. The formation of iodoproteins by direct action of the halogen on various substrates, such as casein, insulin and pepsin, has been brought about primarily to obtain products endowed with metabolic activity or antigoitrogenic potency. These, under certain conditions, induce the formation of thyroxine, its quantity being a function of some variables, the most important of which is the structure of the iodonated protein. The physiological activities of the thyroglobulins and of the artificially iodized proteins are manifold and are due to the presence of thyroxine. The study of the intensity of these actions in relation to their content of the hormone has been the subject of many discussions. The results obtained concerning the antigoitrogenic action of iodocasein and thyroglobulin show that the effects observed are not only related to the content of thyroxine and to the degree of assimilation of the latter but to the rapidity of its reabsorption. The author concluded that the biochemistry of natural and artificial iodoproteins is linked to the biochemistry of iodothyroxine and of the thyroxine.

Medicosurgical Society

At a meeting of the Medicosurgical Society of Pisa, Drs. Tangheroni and Bottone discussed methods of diagnosing spasmophilic diathesis and their clinical value. They applied to infants the hypocalcemia and hyperpnea tests, suggested as diagnostic methods for spasmophilia in adults. They combined the humoral investigation on calcium-phosphorus metabolism with the study of chronaxia and recommended the use of these methods for the diagnosis of spasmophilic diathesis.

Dr. Tarantino reported investigations that show how the synthesis of glycogen performed in vitro by the liver of rats treated with pituitary adrenocorticotropic hormone (ACTH) can take place starting from carbohydrates such as glucose, in addition to protein and lipid derivatives.

Dr. Landi surveyed aseptic necrosis of bone, with special reference to the upper epiphysis of the femur, to the scaphoid and the semilunar bones. These osseous alterations, found in numerous clinical forms, such as osteochondritis and the results of trauma, have in common a disturbance of the blood circulation, and they all lead to the final picture of arthrosis deformans.

Drs. Conti and Andreani reported results of their study on lipemic variations produced by the administration of large doses of pituitary adrenocorticotropic hormone or by prolonged administration of this drug for several days. They observed that an intramuscular injection of large doses is followed by hyperlipemic or hypolipemic reactions, closely related to the neuroendocrine orientation of the patients and to the state of hypophysial function. In patients with clear manifestations of hypopituitarism, there is a constant increase of the total lipids and cholesterols, while rapid diminution of lipids may be observed in patients with hyperpituitarism. The speakers observed a constant diminution of total lipids and cholesterols after a prolonged treatment with pituitary adrenocorticotropic hormone in all cases. The authors are of the opinion that the lipemic and cholesteremic variations induced by adrenocorticotropic stimuli represent manifestations of the general lipid metabolism, induced and sustained by the reactivated function of the adrenal cortex.

Society of Gerontology

The Italian Society of Gerontology and Geriatrics was officially established at a meeting at the Medical Clinic of the University of Florence. Professor Greppi, clinician of Florence, was elected president. The society developed from a group of research workers in this field formed in 1948 through the efforts of Prof. Maurizio Ascoli, clinician of the University of Palermo. The society contributed numerous reports to the First International Congress held at Liège and will participate in the next National Congress of Medicine and Surgery.

BELGIUM

(From a Regular Correspondent)

LIÈGE, Oct. 30, 1950.

Meningitis and Streptomycin

Intensive studies have been devoted to the treatment of tuberculous meningitis with streptomycin. The universities of Brussels (with Dubois, Linz, Van Wien, Govaerts and Durieu), Liège (with Roskam, Plumier, Reginster and their pupils), Louvain (with Van Goidsenhoven and Stevens) and Ghent (with Hooft and Deneve) have contributed to the study of this problem. It seems that there is general agreement that combined treatment by intramuscular and intraspinal or suboccipital injections is important. According to Dubois, this combined treatment with daily intraspinal injection is maintained for 45 days and is followed by a rest period of 20 days. Then follows a second period of 20 days' treatment with daily intramuscular and intraspinal injections and a second rest period of 20 days. The third course consists of treatment for 30 days with intraspinal injections every two days.

In patients undergoing treatment for miliary tuberculosis, the authors performed a spinal puncture every eight days, which sometimes enabled them to detect the meningeal infection before the appearance of the clinical symptoms. In such cases, the combined treatment was instituted and the result of cultures later proved the sound basis of this procedure. Inoculation of guinea pigs, culture of the cerebrospinal fluid and determination of streptomycin levels in the blood and the cerebrospinal fluid were done periodically. The fasting sugar content of the cerebrospinal fluid was determined and then compared with the sugar content of the blood. From these observations during the initial period of the disease, the authors reached the following conclusions: combined treatment arrests the rapid progression of tuberculous meningitis. After the patients have passed the difficult period, the first five months, in which the prognosis is greatly influenced by the early institution of treatment, they show the exterior aspects of convalescence. However, some of these patients are still threatened by serious difficulties, especially by relapse. In addition, the following observations were made: 1. Patients in whom treatment is started more than 15 days after onset have a slight chance of surviving. 2. The existence of paralysis and of a comatose condition at the beginning of treatment indicates usually a fatal prognosis. 3. Prolonged vomiting during treatment indicates unfavorable extension of the disease.

Hooft and Deneve, on the basis of clinical symptoms and results of examination of the cerebrospinal fluid and the eyegrounds, are in favor of prolonging the treatment in certain cases as long as eight or nine months. Maldague reports the following results. The percentage of apparent cures in a group of 39 children, in whom the treatment was started six to fourteen months prior to reporting, was 51. There were two cases with serious, definitive sequels. The outcome in 8 per cent of the children is still doubtful. The death rate is high during the first month of treatment and decreases considerably after the second month. The prognosis for children under two years is particularly unfavorable. The coexistence of miliary tuberculosis does not seem to aggravate the prognosis of meningitis. In 15 of 18 cases of miliary tuberculosis of the lungs, a complete and seemingly definitive roentgen clearing of the lungs was obtained in one to six months, often even in two or three months. Plumier reported the following results: 38 deaths and 26 survivals. The 26 surviving patients included 16 showing a favorable and six an unfavorable course. Of the 10 patients with associated miliary tuberculosis, nine died and one recovered.

Some authors attributed the failures to the formation and development of fibrinous or fibrocaseous deposits rather than to the acquired streptomycin resistance of the bacilli. Van Goidsenhoven believes that, because of the availability of streptomycin, tuberculous meningitis and miliary tuberculosis are no longer hopeless diseases. The two essential factors for the distant prognosis are: (1) early diagnosis and immediate institution of treatment and (2) prolonged combined treatment with daily intramuscular and intraspinal injections. Relapses after cessation of treatment and the late recurrence of the disease toward the end of the treatment threaten the later prognosis of convalescent patients, but the initial tuberculous localization always constitutes a threat. The more important local complications during the course of intraspinal therapy are meningeal hemorrhage, pachymeningitis and hydrocephalus. The more serious toxic manifestations are auditory and vestibular disturbances. With the dosage used at present, total deafness occurs rarely. A likelier toxic manifestation is insufficiency of renal function caused by abnormally high levels of streptomycin in the blood.

The Red Cross in the Congo

The Red Cross in the Congo, which is a section of the Belgian Red Cross, recently published reports on its activity during 1948 and 1949, which extended to the following spheres: care of lepers, venereal diseases, medical assistance to the indigent, creation and maintenance of training schools for nurses and teaching the essentials of hygiene to the native population. Protection of children is also a large part of its activities. Outpatient consultation services and clinical services have been established for the care of nursing infants. A complete medicosocial service has been established, which has been extended by the creation of a workshop for the mothers of the native population. The workshop makes children's clothes for needy members of the service. That the native women gladly devote part of their time to the Red Cross is an encouraging sign, because the feeling of mutual help and devotion is little developed among natives beyond the restricted circle of the family or of the tribe.

Death of Prof. André Gratia

The death of Professor Gratia has deeply moved the medical profession in Belgium. Just 57 years old, he died while still very active in scientific work. Since 1933, he was professor of bacteriology at the University of Liège and director of the bacteriologic service of Malvoz Institute. As corresponding member of the Royal Academy of Medicine of Belgium, he distinguished himself particularly by his investigations on bacteriophages, plant viruses, immunity to anthrax and antibiotics. In 1946 the government commissioned him to direct a center of research on penicillin in Liège.

COLOMBIA

(From a Regular Correspondent)

Bogotá, Oct. 20, 1950.

Glucose Blood Levels and Phosphoric Esters of Thiamine

Drs. Gonzalo Montes Duque and Julio Cárdenas Araque presented, at the last session of the National Academy of Medicine, September 28, the result of preliminary experiments on glucose levels in man and animals after the administration of the pyrophosphoric ester of thiamine (cocarboxylase) and of the orthophosphate ester of thiamine. Dr. Cárdenas thought that certain disorders of the nervous system, such as schizophrenia, might be due to a disturbance of carbohydrate metabolism of the neurons. The theory is supported by the favorable results obtained by the use of insulin shock in some cases of schizophrenia. The speakers studied the multiple factors which control cerebral metabolism and tried cocarboxylase in the treatment of schizophrenia. Their results suggest that cocarboxylase affects carbohydrate metabolism. They found that administration of cocarboxylase, either orally or intraperitoneally, to mice regularly produced convulsions. Since the pyrophosphoric radical has a hypocalcemic action which might have accounted for the observed convulsions, sodium pyrophosphate was tested on another group of animals. The results were the same; the animals had convulsions. Since the orthophosphoric radical does not cause hypocalcemia, a new compound was synthesized in which the pyrophosphoric radical was replaced by an orthophosphoric radical. Thiamine orthophosphate given intraperitoneally induced convulsions in three of the four mice treated. No convulsions occurred when sodium orthophosphate was administered, indicating that the orthophosphoric radical, by itself, has no convulsive action, whereas, the orthophosphate of thiamine has such an action.

The authors then tested these substances on clinical and experimental diabetes mellitus; results were promising. Subcutaneous and oral administration of thiamine pyrophosphate to rabbits caused a decided fall in blood sugar levels, while in human cases of diabetes mellitus the oral administration of thiamine pyrophosphate and thiamine orthophosphate caused a reduction of blood sugar values and a disappearance of glycosuria. Six patients, to whom different doses of phosphoric esters of thiamine were administered, were observed. Sugar levels in the urine and in the blood were determined during the first three hours or during the first 24 hours following administration of the esters. The results were similar: diminution of sugar in the blood and disappearance of sugar from the urine one hour after administration. These experiments seem to indicate that the phosphoric esters of thiamine have a favorable action on carbohydrate metabolism. The action of the phosphoric esters seem to be similar to that of insulin. It is possible that these compounds can replace insulin and that insulin acts through the phosphorization of the thiamine. This interpretation would agree with Houssay's observation that the phosphate levels in the blood plasma fall through the action of insulin. R. Boulin, P. Uhry and co-workers have shown that during the diabetic coma the most important disturbance of carbohydrate metabolism is the increased pyruvic acid level in the blood, on which insulin has no effect. These authors used cocarboxylase and reported good results in 10 cases of diabetic coma. The results of Montes and Cárdenas, regulation of blood sugar by oral administration of cocarboxylase, and those of Boulin and Uhry, diminution of pyruvemia with intravenously administered cocarboxylase, prove the efficacy of this compound in the treatment of diabetes.

Bureau of Medical Economic Research

MATERNAL MORTALITY IN THE UNITED STATES IN 1949

FRANK G. DICKINSON, Ph.D.
and
EVERETT L. WELKER, Ph.D.
Chicago

The downward trend of maternal mortality in the United States continued through 1949, according to data collected from the state health departments. Provisional reports received in correspondence with the states furnished information on the numbers of live births and maternal deaths for 47 states and the District of Columbia. With the 1948 data for the nonreporting state, Rhode Island, an estimated maternal mortality rate of slightly less than one maternal death per 1,000 live births was obtained for the United States in 1949. The maternal mortality problem in the United States is no longer a serious national problem but is, rather, one for local action in those areas in which maternal mortality rates are still relatively high. The rate for the United States has been declining rather steadily since 1933, the first year in which all the states were in the birth and death registration areas. The rate for 1933 was 6.2 and the rates for the intervening years were as follows:

1934	5.9	1939	4.0	1944	2.3
1935	5.8	1940	3.8	1945	2.1
1936	5.7	1941	3.2	1946	1.6
1937	4.9	1942	2.6	1947	1.3
1938	4.4	1943	2.5	1948	1.2

In 1933 the rate for all deaths in Sweden was 3.1 and for white deaths only in New Zealand, 4.4. When the 1949 rates are published for Sweden and New Zealand they, also, will probably be slightly below the provisional rate of one for the United States. Hence it should be clear to the public that the United States, with its variations in climate and population and with its extreme size, has just about caught up with these two small healthy countries with homogeneous populations. In fact, differences in future maternal mortality rates between these three and others of the healthier nations are likely to be so small in magnitude that they could be a result of minor errors in reporting births and deaths and in erroneously attributing some deaths of women (that is, in coding) to maternal causes.[1] In at least three ways 1949, therefore, marks an end of an era in maternal mortality: The United States is the first large nation to push its maternal mortality rate slightly below the apparently irreducible minimum of one maternal death per 1,000 live births; critics of the quality and quantity of medical care in America will probably no longer attempt to make unfavorable comparisons between the United States and any nation, large or small, in the matter of maternal mortality rates, and 1949 was a transition year in coding the causes of death, a transition from the fifth to the sixth revision of the International List.

FIFTH AND SIXTH REVISIONS OF THE LIST

In this study an attempt has been made to estimate the number of maternal deaths during 1949 on the basis of both the fifth and the sixth revisions of the International List in order to provide 1949 rates comparable to the maternal mortality rates for the preceding 10 years and to the rates of future years; our major interest is in comparisons with the 10 preceding years. The sixth revision of the International List went into effect in some states on Jan. 1, 1949. Of the 49 states, including the District of Columbia as a state for this purpose, only 23 states reported 1949 maternal deaths on the basis of both the fifth and sixth revisions of the list. Only in the United States was the sixth revision widely used before Jan. 1, 1950, the "effective" date for most of the other nations. Thus 1949 was a year of transition in coding the causes of death.

As might be expected, there is some difference of opinion as to the precise effect of the new list on the number of maternal deaths, but there is general agreement that the number of maternal deaths will be fewer.[2] Much will depend on the care taken by the physician when specifying the underlying cause of death on the new death certificate form. The present problem is to estimate the probable effect and to express it as a percentage of the fifth to the sixth and vice versa. Table 1 presents the number of maternal deaths in the 23 states where the coding was done under both the fifth and sixth revisions. The total number of maternal deaths in these 23 states for 1949 coded under the fifth revision was 1,316; the number under the sixth revision was 1,244; thus the latter was 94.5 per cent of the former and the former 105.8 of the latter (bottom row, table 1). On the basis of this information for these 23 states, we concluded for the purposes of this paper that for every 100 maternal deaths in 1949 coded under the sixth revision there would have been approximately 106 deaths under the fifth revision and for every 100 maternal deaths under the fifth revision there would have been approximately 95 deaths under the sixth revision.[3] Consequently, we shall call 106 and 95 per cent our comparability ratios, with the understanding that they are not based on maternal deaths in all states in 1949. The maternal mortality rates for the United States in 1949, 1.0 (0.98) based on the fifth revision of the International List and 0.9 (0.93) based on the sixth revision, must be considered provisional or estimated rates.[4] The "true" national rate for 1949 on the basis of either the fifth or sixth revision may never be known. (The rate for the 45 states which reported the number of maternal deaths under the sixth revision was 0.93.)

Director (Dr. Dickinson) and Associate in Mathematics (Dr. Welker), Bureau of Medical Economic Research, American Medical Association.

Virginia Van Heule Horan and Helen Hulings Boyles, research assistants in the Bureau of Medical Economic Research, prepared the tables.

[1] The latest available published rates for the nations with the lowest maternal mortality rates are as follows: Australia (excluding aboriginals) 1947, 1.9; Canada 1948, 1.5; Denmark 1948, 0.9; England and Wales 1947, 1.2; Finland 1947, 2.1; Netherlands 1947, 1.4; New Zealand (excluding Maoris) 1947, 1.1; Norway 1947, 1.5; South Africa (rate per 1,000 [total] births for Europeans only) 1947, 1.4; Sweden 1945, 1.3, and Switzerland 1947, 1.8.

[2] Erhardt, C. L., and Weiner, L.: Changes in Mortality Statistics Through the Use of the New International Statistical Classification, Am. J. Pub. Health. **40:** 6 (Jan.) 1950.

[3] Computation of the standard deviation for either of these two national comparability ratios, 1.06 and 0.95, would be misleading because the maternal deaths used in computing these ratios are not a random sample of the universe. Hence the reliability of each of these two ratios cannot be tested statistically. If these 23 state ratios (fifth to sixth revisions) were arrayed in descending order, it would be evident that the highest values are for the states with the largest number of maternal deaths. The ratios are greater than 1.08 for Georgia, Illinois, New York and North Carolina. On the other hand, the ratio is relatively low in all the states reporting fewer than 50 maternal deaths. The median, mode and mean of these 23 state ratios are 1.000, 1.000 and 1.016. Although a difference in this direction might be rationalized, the difference seems to be too great to result from purely random factors. Would the national ratio be 1.07 if Pennsylvania and Ohio, each with more than 100 maternal deaths, had coded their maternal deaths on the basis of both revisions? Since our sample includes fewer than one-half the maternal deaths in 1949, our comparability ratio must be used cautiously by statisticians. We have, therefore, deliberately rounded it to 1.06 as a warning to readers that they should await the findings of the National Office of Vital Statistics, which will code from the death certificates all maternal deaths on the basis of both the fifth and sixth revisions. Some authorities predict that this comparability ratio may be as high as 1.10. All we can say is that on the basis of our (biased) sample it is 1.058, which we have rounded to 1.06; conversely, we have rounded the ratio of the sixth to the fifth revision data from our computed national ratio of 0.9453 to 0.95. These two rounded values have been used in preparing the estimated rates—three in column 4 and 22 in column 5 of table 2 for those states which did not code on the basis of both the fifth and the sixth revisions.

[4] The maternal mortality rate overestimates the true risk of death from these causes because the rate is based on registered births. If, in a given year, the estimated number of unregistered births is 5 per cent of the registered births the "correct" maternal mortality rate is the rate based on registered deaths divided by 1.05. While it is necessary in historical comparisons to use the traditional maternal mortality rate, the probability of surviving pregnancy, childbirth and the puerperium in any one year—say the current year—should be based on all live births, not merely on registered births. For a discussion of the tendency of the maternal mortality rate to overestimate the true risk of death from maternal causes see pages 48-49 of Vital Statistics Rates in the United States, 1900-1940, Bureau of Census, United States Department of Commerce, Government Printing Office, Washington, 1943. An unpublished report of a sample developed by the National Office of Vital Statistics in the process of coding the causes of all deaths in 1949 provides an entirely different reason for our believing that our estimated national maternal mortality rate of 0.98 is too high.

But the rates for all states in 1950 will presumably be based on the sixth revision. Hence the 1949 rates estimated on the basis of the fifth revision are more useful in making comparisons with rates for earlier years, and those based on the sixth revision, with 1950 and future years.

Table 2 presents the basic data on live births and maternal deaths in each state and in the United States for 1949 as well as the maternal mortality rates for 1949, 1948 and 1933. The reported number of maternal deaths coded under the fifth revision (column 3) and under the sixth revision (column 2) are presented; likewise the reported or estimated (by the comparability ratio) maternal mortality rates under the fifth and sixth revisions are shown in columns 5 and 4. No reference will be made hereafter in this paper to rates based on the sixth revision.

RATES AND RANGE DECLINE

In the comparison of the state rates in column 5 (fifth revision) for 1949 with those for 1948 in column 6, declines are indicated for 35 states, including the District of Columbia. For five states the rates were unchanged and for only 9 were there increases from 1948 to 1949. Most of these increases were very slight. Many of the individual states have rates which are truly astounding.

Table 1.—*Comparability Ratios for Twenty-Three States*

State	Number of Maternal Deaths: 5th Revision (1)	Number of Maternal Deaths: 6th Revision (2)	Ratio 5th to 6th (3)
Delaware	5	5	1.000
District of Columbia	15	17	0.882

Virginia	88	84	1.048
Washington	36	36	1.000
West Virginia	53	52	1.019
Wisconsin	50	47	1.064
Totals	1,316	1,244	.....
Ratio of totals	.....	.....	1.058

Our present national rate of 1.0 for 1949 compares favorably with the 0.9 reported for Denmark for 1948, the lowest ever recorded by any nation in published reports now available. In the United States there were 26 states with rates lower than this record of 0.9. It has been previously pointed out in many articles that international comparisons between the United States and the small countries with homogeneous populations are somewhat strained. In spite of the handicap placed on the United States by such comparisons, it is gratifying to see that these obstacles have been almost entirely overcome in the problem of maternal mortality and that we are now apparently almost tied with the leader. It is even more startling that 30 states, more than one half of the total, have rates actually lower than 1.0. It should also be noted that these low rates are not chance occurrences for 1949 only, because many of these states have been consistently better than any nation in the world. In many instances the populations of the states in question are larger and less homogeneous than those of the small nations with the outstanding health records frequently cited in the literature.

Even in the 17 states with rates over 1.0, childbearing is becoming quite safe. Only two states have rates above 2.0; Mississippi has a rate of 2.4 and Alabama, a rate of 2.1. There are 14 states with rates within the range 1.1 to 1.9 inclusive.

UNITED STATES	3,553,551	3,291	3,482	0.93	0.98	1.2	6.2

A large majority of these 14 states have shown a decline from 1948 to 1949 in maternal mortality rates. Even the highest state rate for 1949 of 2.4 was about one-half the lowest state rate in 1933, a rate of 4.3 maternal deaths per 1,000 live births.

§ 1948 data.

As the rates decline, uniformity in state rates is being approached more rapidly than might be expected. In 1933 the range from the lowest to the highest state rate was 7.2 maternal deaths per 1,000 live births, while in 1949 the range had been reduced to 2.0, a decline of 72 per cent. The present low national rate has been achieved by reductions in all the states and not just by reductions in the more favored states. It has been the result of the efforts in every section of the nation to reduce the number of maternal deaths from each cause.

UNSTABLE RATES

From the statistical viewpoint, the small number of maternal deaths in some states has created a new problem in analyzing state maternal mortality rates. Only four maternal deaths occurred in Nevada and in Vermont in 1949. One maternal death, more or less, in these states would have resulted in a 25 per cent change in the maternal mortality rate. The situation was even more unstable in the state of Wyoming, where only three maternal deaths occurred. One can reduce this instability of maternal mortality rates for some of the states by considering three year averages centered on the middle year. Presumably the three year average for 1950-1952 will be for the first future trio of years which would not involve the coding difficulties; that is, the sixth revision would be used in all three years.

† New England (Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut). Middle Atlantic (New York, New Jersey, Pennsylvania). East North Central (Ohio, Indiana, Illinois, Michigan, Wisconsin). West North Central (Minnesota, Iowa, Missouri, North Dakota, South Dakota, Nebraska, Kansas). South Atlantic (Delaware, Maryland, District of Columbia, Virginia, West Virginia, North Carolina, South Carolina, Georgia, Florida). East South Central (Kentucky, Tennessee, Alabama, Mississippi). West South Central (Arkansas, Louisiana, Oklahoma, Texas). Mountain (Montana, Idaho, Wyoming, Colorado, New Mexico, Arizona, Utah, Nevada). Pacific (Washington, Oregon, California).

‡ Based on fifth revision.

Another method would be the grouping of states into divisions such as the nine census divisions as shown in table 3. The highest rate, 1.8, occurs in the East South Central division; four divisions are tied at the lowest rate, 0.7. These rates indicate that the major problem in maternal mortality occurs in the South. The racial composition in the southern states may explain some of the excess of their rates above those of the other divisions. The major disadvantage in the use of nine divisions lies in the fact that maternal mortality should now be considered primarily a local problem and the health leaders in individual states (and large cities) will still be interested in comparisons between states rather than between groups of states. It should be noted that apparently no nation in the world has yet achieved a maternal mortality rate as low as 0.7, the rate for four divisions.

The maternal mortality rate is a crude rate rather than an age-specific rate. The rate, however, is closely associated with the age of the mother. Table 4 shows the age distributions of maternal deaths in 1933 and 1948 together with the age-specific maternal mortality rates. Table 5 shows the number and percentage distributions of all live births by the age of the mother. The safest childbearing age is still between 20 and 29 years. The age-specific mortality rates for the two age groups in this range differed much more in 1933 than they did in 1948. In 1933 the maternal mortality rate in the age group 20 to 24 years was 4.3 maternal deaths per 1,000 live births, 0.8 below the 5.1 rate for the age group 25 to 29 years; in 1948 these two rates were 0.7 and 0.9, respectively, a difference of only 0.2. The rates differed so greatly in 1933 that it is possible to say that only in the age group 20 to 24 years was the risk of maternal death relatively low. This age range in 1948 can be extended to include ages 20 to 29, or even ages 15 to 29. In 1948 a sharp difference in the risk of maternal death occurred beyond the age of 30. In 1933 the situation was somewhat different, with relatively high age-specific rates, even in the lower age brackets, and no sharp break occurring between age groups except above the age group 40 to 44. It seems obvious from the age-specific rates that the decided reduction in maternal mortality has been well distributed throughout the entire range of ages. The medical profession would like to make childbearing safer at all ages, but for the older mothers and for those under age 15 the problem will continue to be rather difficult.

* Source: Birth, Stillbirth, and Infant Mortality Statistics, 1933, Bureau of the Census, U. S. Department of Commerce, Washington, 1936, p. 111. Vital Statistics of the United States, 1948, Part II, National Office of Vital Statistics, Public Health Service, Federal Security Agency, Washington, 1950, p. 100.

The age of mothers has declined slightly between 1933 and 1948. (The total numbers of live births were 2,080,000 in 1933 and 3,535,000 in 1948.) If one considers only live births, in 1933 the mother's average (mean) age was 27.3 years; in 1948 the average was only 26.6 years. The median ages were 26.5 years and 25.9 years, respectively. The percentage distributions are shown in table 5. The most notable changes occurred in the age groups 20 to 24 and 25 to 29. In 1948 each of these two groups was about two or three percentage points above the values recorded in 1933. Conversely, the percentage of mothers over the age of 34 decreased from 15.1 per cent in 1933 to 10.7 per cent in 1948, a decrease which partially explains the reduction in the maternal mortality rate. This age factor was probably more than counterbalanced by the increase in the percentage of first births from 31.7 per cent to 35.6 per cent. The tremendous reduction from 6.2 in 1933 to 1.2 in 1948 (in the crude rate) is, therefore, primarily due to the reduction in the age-specific rates and is only mildly influenced by the counterbalancing changes in age and first births. This is obvious if one notes that no age-specific mortality rate in 1933 was even close to the 1.2 recorded in 1948 for the entire United States In fact, the risk of maternal death in the age group 45 to 49 in 1948 was less than in the age group 30 to 34 in 1933.

CAUSES IN 1933 AND 1948

Table 6 shows basic data for an analysis of maternal mortality by cause in 1933 and 1948. These two years were chosen because 1933 is the first year for which all the states were in both the death and birth registration area and 1948 was the last year for which data by cause are available; 1948 is also the last year for which the fifth revision of the International List was generally used. Deaths in 1933 were coded on the basis of the 1929 (the fourth) revision of the International List. Hence we found it necessary in preparing table 6 to make certain adjustments[5] to allow for the changes in coding which went into effect in 1939 with the fifth revision. Although the same groups of code numbers for maternal deaths, 140-150, were used in both the fourth and fifth revisions, there were differences in the exact types of causes encompassed by some of these 11 code numbers. This procedure required certain combinations of some of the code numbers (140-150) of the fifth revision in order to obtain comparable groupings of maternal deaths by cause in 1933 and 1948. The combinations of causes were made in terms of the fifth rather than the fourth revision (footnote to table 6).

Table 6 shows the number of maternal deaths, the maternal death rate and the percentage of deaths attributed to each of seven groups of causes for 1933 and 1948, together with the percentage decrease in rates from 1933 to 1948. The totals for all causes of maternal deaths are presented in row 1. The percentage of maternal deaths attributed to "abortion with mention of infection" (row 2) was 15.8 in 1933 and less than half that figure, 7.0, in 1948 (columns 3 and 6). "Abortion without mention of infection" (row 3) and "ectopic gestation" (row 4) were of nearly equal importance in both years. "Hemorrhage of pregnancy and of childbirth and puerperium" (row 5) increased in importance from 10.4 per cent in 1933 to 18.8 per cent in 1948. There was an increase of 3 per cent in "toxemias of pregnancy and puerperium" (row 6), the leading cause in 1948 and the second in 1933, between the two years. There was a decrease of 3 per cent in "other diseases and accidents of pregnancy; infection during childbirth and puerperium" (row 7), the leading cause in 1933 and the second in 1948. There was no change in "other accidents of childbirth; other and unspecified conditions of childbirth and puerperium" (row 8).

There was a decided decrease in the rates for each of the causes in the interval from 1933 to 1948. The percentage decreases (column 7) ranged from 66 for hemorrhage of pregnancy, childbirth and the puerperium (row 5) to 92 for abortion with mention of infection (row 2). This gives some support to the belief that the reduction in maternal deaths from hemorrhage is more difficult to achieve than reduction in maternal deaths from some of the other causes. Particularly striking is the reduction in the maternal mortality rate from abortion with mention of infection (row 2) from 0.98 (column 2) in 1933 to 0.08 (column 5) in 1948. The second largest percentage reduction in the rate was 84 for other diseases and accidents of pregnancy and infection during childbirth and the puerperium (row 7). Since accidents account for a small portion of the deaths from this group of causes, this decrease is primarily a decrease in deaths due to infections. These figures suggest that newer technics, more effective drugs and increased hospitalization are assisting in the reduction of maternal deaths due to infections.

TABLE 6.—*Number and Percentage of Total Maternal Deaths, Mortality Rates and Percentage Declines, by Cause; 1933 and 1948* *

	1933			1948			
Cause †	Number of Deaths (1)	Deaths per 1,000 Live Births (2)	Percentage of Total (3)	Number of Deaths (4)	Deaths per 1,000 Live Births (5)	Percentage of Total (6)	Percentage Decrease in Rates from 1933 to 1948 (7)
1. Diseases of pregnancy, childbirth and the puerperium (140-150)	12,885	6.19	100.0	4,122	1.17	100.0	81
2. Abortion with mention of infection (140)	2,037	0.98	15.8	289	0.08	7.0	92
3. Abortion without mention of infection (141)	640	0.31	5.0	207	0.06	5.0	81
4. Ectopic gestation (142)	610	0.29	4.7	243	0.07	5.9	76
5. Hemorrhage of pregnancy and of childbirth and puerperium (143, 146)	1,339	0.64	10.4	773	0.22	18.8	66
6. Toxemias of pregnancy and puerperium (144, 148)	3,055	1.47	23.7	1,102	0.31	26.7	79
7. Other diseases and accidents of pregnancy; infection during childbirth and puerperium (145, 147)	3,409	1.64	26.5	964	0.27	23.4	84
8. Other accidents of childbirth; other and unspecified conditions of childbirth and puerperium (149, 150)	1,795	0.86	13.9	544	0.16	13.2	81

† The code numbers in parentheses are from the Manual of the International List of Causes of Death, fifth revision, Bureau of the Census, U. S. Department of Commerce, Washington, 1940. The code numbers 143, 146 from the 1938 revision correspond with the code number 144 from the 1929 revision. The code numbers 144, 148 from the 1938 revision correspond with the code numbers 146, 147 from the 1929 revision. The code numbers 145, 147 from the 1938 revision correspond with the code numbers 143, 145, 148 from the 1929 revision.

Since neither of us is a physician, we asked two well qualified obstetricians to comment on table 6 for the purpose of presenting an informed medical opinion of the reasons for the sharp declines in the seven groups of causes of maternal mortality. These two physicians prefer to remain anonymous. Their statement follows:

"In reviewing table 6 from the viewpoint of possible factors which could account for the reduction in mortality between 1933 and 1948 from the seven groups of causes, it is possible to summarize the factors under three definite categories: (1) care, that is, improved medical care of pregnant women, particularly intranatal and postnatal care in hospitals, which involves better training on the part of physicians and some improvements in methods which have been devised since 1933; (2) antibiotics and blood, that is, the development of antibiotics and the greater availability and use of blood, blood substitutes and blood derivatives since 1933, and (3) earlier diagnosis, that is, provision for better prenatal care for a larger percentage of mothers than in 1933 making it possible to recognize unfavorable conditions in a higher percentage of pregnant women than in 1933.

[5] Dunn, H. L., and Shackley, W.: Comparison of Cause-of-Death Assignments by the 1929 and 1938 Revisions of the International List: Deaths in the United States, 1940, Department of Commerce, Bureau of the Census, Vital Statistics-Special Reports **19:** 165 (June 14) 1944.

"We are listing below for each of the seven groups of causes in table 6 the one or more of these three factors primarily responsible for reductions in mortality and in the order of their importance.

Row 2 (140). Abortion with mention of infection: antibiotics and blood, plus care.
Row 3 (141). Abortion without mention of infection: care.
Row 4 (142). Ectopic gestation: early diagnosis; care (surgery); blood.
Row 5 (143, 146). Hemorrhage of pregnancy and of childbirth and puerperium: care; blood.
Row 6 (144, 148). Toxemias of pregnancy and puerperium: early diagnosis; care.
Row 7 (145, 147). Other diseases and accidents of pregnancy; infection during childbirth and puerperium: antibiotics; care.
Row 8 (149,150). Other accidents of childbirth; other and unspecified conditions of childbirth and puerperium: care.

"It will be noted that only the third factor, care, is given as a factor in the explanation of a sharp decline in maternal mortality from each of the seven groups of causes. Early diagnosis or prenatal care plays a significant role in ectopic gestation and toxemias of pregnancy and in assuring adequate size of the birth canal for safe delivery. Although educational programs for expectant mothers have doubtlessly been effective in reducing deaths from abortion with and without infection, the antibiotics and the availability of blood have been primarily responsible for the reduction in maternal deaths due to other diseases and accidents of pregnancy and infections during childbirth and the puerperium (row 7).

TABLE 7.—*Regional Maternal Mortality Rates in the United States by Cause, 1948 (Deaths per 1,000 Live Births)**

Cause †	United States (1)	New England (2)	Middle Atlantic (3)	East North Central (4)	West North Central (5)	South Atlantic (6)	East South Central (7)	West South Central (8)	Mountain (9)	Pacific (10)
1. Diseases of pregnancy, childbirth and the puerperium (140-150)	1.17	0.81	0.89	0.87	0.85	1.69	2.01	1.57	1.17	0.75

† The code numbers in parentheses are from the Manual of the International List of Causes of Death, fifth revision, Bureau of the Census, U. S. Department of Commerce, Washington, 1940.
‡ Death before delivery.

"It should also be noted that the two largest numbers of maternal deaths for 1933 and 1948 are found in rows 6 and 7. Ectopic gestation (row 4) and hemorrhage of pregnancy and of childbirth and puerperium (row 5) are the only causes of maternal deaths in 1948 which show a percentage decline in the rate (column 7) markedly less than the over-all decline of 81 per cent in the entire maternal mortality rate. It is in this area of the risk of childbearing that prenatal care may make its greatest contribution; but the physician will still play the primary role since it is only on his interpretation of findings that treatment will be given. If the patient will come early to the physician, ectopic gestation may be discovered early. If the patient is taught that any spotting or bleeding during pregnancy is potentially dangerous and that she should consult her physician at once, the mortality can be further reduced. If the patient is making the properly spaced visits to the physician so that a profile of her blood pressures, urine examinations and weight has accumulated on her chart, the physician can make the diagnosis of toxemia of pregnancy relatively early.

"In every one of these situations described by these seven groups of causes of maternal mortality, the physician is the key factor. The purpose of health education in all of its ramifications is, therefore, to get the patient to the physician early in pregnancy. In summary, this analysis of the reduction in the mortality rates by seven groups of causes indicates that the improved training and the increased skill of the physician are by far the most important factors."

The rates by cause for the nine geographic divisions are shown in table 7. (The difficulty faced in the compilation of table 6—translation of coding of the causes of death in the 1929 revision to the 1938 revision of the Manual of the International List of Causes of Death—does not arise in table 7, as the data are for 1948 only.) There is considerable variation in the rates by cause in the different divisions. The high maternal mortality rate for the East South Central division is apparently due to excessive numbers of deaths from toxemias of pregnancy (row 6) puerperal toxemias (row 10) hemorrhage of childbirth and the puerperium (row 8) and infection during childbirth and the puerperium (row 9). Physicians in the individual states are undoubtedly aware of the specific problems within their areas and continued reduction in these rates can be anticipated.

THE BASE—10,000 OR 1,000

Now that the maternal mortality rates for the 30 states and for the entire nation are less than one maternal death per thousand live births, there will undoubtedly be some tendency to make the rate base 10,000, even 100,000, live births instead of the traditional 1,000 live births. The rate based on 10,000 live births would be 10 instead of the 1.0 based on the traditional 1,000. The number of maternal deaths per 10,000 live (or total) births has rarely been used as the maternal mortality rate for a nation. Although the avoidance of decimals in rates may have some small merit, it seems to us that a change in the rate base from 1,000 to 10,000 live births would be unwarranted and would probably be misleading in any subsequent historical comparisons with earlier years. Revisions of the International List complicate historical comparisons; a change in the rate base would be another complication.

Since all maternal deaths are included in the number of maternal deaths whether the pregnancy was terminated by an abortion (miscarriage), a stillbirth or a live birth, there is, admittedly, some inconsistency in using only live births in the denominator. But it does not seem advisable at this time to add fetal deaths, which have been excluded heretofore, largely because of the lack of accurate and complete data.

In the whole range of vital statistics the maternal mortality rate is a peculiar rate. It is a crude rather than an age-specific rate. It has been customary to refer to the number of deaths —from all causes combined—per 1,000 persons at all ages as the crude death rate for the whole nation. The age distribution of mothers is limited and is not subject to such great changes as could and have occurred in the entire population. The maternal mortality rate is, therefore, not as "crude" as the crude death rate for the entire population. Expressing the maternal mortality rate as the number of deaths per 1,000 live births has, therefore, been consistent with the practice in regard to the crude death rate for the entire population.

The universe for maternal deaths is not the entire population but the number of women who are delivered during the course of the calendar year. It is customary to use 100,000 persons as the rate base in the computation of the mortality rate from a single cause or a group of causes—pneumonia or heart diseases. But this number of persons, the exposure group, would have no particular bearing on the problem of measuring maternal deaths (the puerperal rate). Even if the rate base were 100,000 females or 100,000 females at the childbearing ages, the resulting rate for a particular calendar year would be rather meaningless as a measure of probability. There would be, therefore, some slight precedent for using 100,000 live births in the computation of future national maternal mortality rates but little, if any, for using 10,000.

The disadvantage of making changes in the methods or data used in computing maternal mortality rates seem to outweigh the advantages, notably the elimination of the awkwardness of a second decimal place in the rate.

COMMENT

It must be remembered that maternal mortality rates are influenced by a variety of factors which vary from state to state. The inherent problems in certain areas of the United States are far more complicated than those in other areas. For this reason it is entirely possible that the records made by some of these states still having higher maternal mortality rates may represent an accomplishment in social progress even greater than that recorded by states reporting the lower maternal mortality figures. Nevertheless, we can see that local authorities, well able to analyze the situation in their own community, are presented with a tremendous opportunity for community service in those states where maternal mortality still maintains a relatively important position in the health picture.

SUMMARY

1. For the first time in history a large nation apparently had so few maternal deaths in relation to the number of live births in 1949 that the maternal mortality rate was below one.

2. In computing this estimate of the maternal mortality rate for the United States in 1949, it was estimated that the number of maternal deaths under the fifth revision of the International List was approximately 6 per cent greater than under the sixth revision.

3. A comparison of the maternal deaths by cause in 1933 and 1948 shows somewhat similar rates of decline except for hemorrhage of pregnancy, childbirth and the puerperium. The authors believe it would be inadvisable to shift from a base of 1,000 live births to a base of 10,000 live births in order to avoid decimal values now that the mortality rate has reached such low levels. Finally, it is good to know that the chances of an expectant mother surviving pregnancy, childbirth and the puerperium in the United States and in a few small countries are now 999 out of 1,000. The risk of dying in childbirth is now approximately one seventh of what it was a generation ago.

4. But we would be misinterpreting the nature of medical progress if, at this time, we did not call attention to the other side of the story. This triumphant conquest of the causes of maternal mortality will bring new challenges to future medical progress. It is to be earnestly hoped that when these mothers become, 20 to 50 years thereafter, potential candidates for the "older" causes of death that considerable gains will have been made in reducing the toll from these older causes. It is the disturbing premise of the practice of medicine that the physician cannot win. He can only raise the average age at death and increase the proportion of people who succumb to the older causes of death. But in providing more years of useful life to expectant mothers, the members of the medical profession and their auxiliary aids have contributed greatly to human and social progress in an era of wars and threats of war.

Medical Motion Pictures

A Place in the Sun. 16 mm., color, sound, showing time 25 minutes. Prepared by Peter Cohen, M.D., Supervisor, Cerebral Palsy Program for Northern California, University of California School of Medicine. Produced in 1950 by Jonathan Musser for the Junior League of San Francisco. Procurable on loan from the Junior League of San Francisco, Inc., Mark Hopkins Hotel, San Francisco.

This film depicts the cerebral palsy program in California. It shows the special examinations that are done in a cerebral palsy clinic to properly evaluate the child with cerebral palsy. It also goes on to show the various aspects of the program in a residence school for affected children, indicating the need for consideration of the whole child and the family. It demonstrates the activities in such a school, that is, physical, occupational and speech therapy, as well as the educational program. It also indicates how the program can be continued in the child's own community.

The presentation is free from unction and overacting. It shows follow-up and home care with the parents, to aid in the transition from the residential school to the home. The emphasis—an integrated one—on a combined therapy, including education and psychological evaluation, is especially good. Professional guidance is evident throughout, and the film gives evidence of authoritative, technical advice and emphasizes the importance of medical supervision.

Although this film will probably be most helpful in gaining the support of various lay groups for schools of the sort described, it has informative and inspirational value and could be shown profitably to almost any mature audience. The nonprofessional person will gain a real appreciation of the difficulties presented by these patients. Nurses, medical students and technicians will also be interested.

The narration is simple. There is no pretense of the film being a "high-pressured" production, but rather informative in a natural, easy manner. The photography is fair to good.

Diagnosis of Uterine Malignancies: 16 mm., sound, color, showing time 12 minutes. Prepared by Dr. Louis Scheffey, Dr. Theodore Eberhard and Dr. Warren Lang, Department of Obstetrics and Gynecology, Jefferson Medical College, Philadelphia. Produced in 1950 by the Jefferson Medical College through a grant for cancer teaching from the National Cancer Institute. Procurable on loan from the American Cancer Society or Jefferson Medical College, 1025 Walnut Street, Philadelphia 7.

The purpose of this motion picture, according to the authors, is to accent the importance of pelvic examination for the detection of pelvic cancer and to illustrate the proper technics, particularly those usable in the office of the physician. The important aspects and the special technical maneuvers for a pelvic examination are discussed and demonstrated by a physician doing a complete pelvic examination. The technic in taking a smear for a Papanicolaou study is then shown. The performance of a curettement of the uterine cavity and two circular biopsies of the cervix are also shown.

The value of rectal examination for determination of the extent of malignant infiltration, or detection of infiltration which might occur in the presence of a benign-looking external cervix, was left out entirely. Although the smear specimen for cytological examination was excellent, the discussion of the preparation was poor. The thinning out of the specimen and the fixation in alcohol and ether were not mentioned. The Papanicolaou smear procedure should precede the pelvic examination, as the use of lubricants in making this examination tends to wipe out the cancerous cells. The importance of endocervical curettage was entirely omitted. The importance of the finding of induration and friability of tissue, detected on palpation, and the use of a probe are also missing. Although the Schiller tincture test is included, the procedure and preparation are not carried out according to accepted technics. There should be included a reason for the performance of conization with a sharp scalpel in preference to diathermy. Induction and withdrawal of the tenaculum to avoid pinching and pulling constitute good advice.

If this film was better organized and more complete, it would have been a valuable aid in teaching general practitioners and medical students the importance of proper examination of the pelvis to detect early cancer. The photography is good; however the entire production is poorly organized.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Powers of State Board of Health in Licensing Chiropractic Hospitals.—This was an action to review an order of the state board of health revoking the plaintiff's license to operate a chiropractic sanitarium. From a judgment in the trial court sustaining the board's action, the plaintiff appealed to the Supreme Court of Colorado.

In 1943 the state board of health issued to the plaintiff a temporary provisional license to operate a sanitarium with the following conditions: 1. Maternity cases shall not be received. 2. Surgery will not be performed. 3. Drugs or medicines shall not be administered. 4. No contagious or infectious cases will be admitted or treated. 5. The name "hospital" shall not be used in describing or designating the institution. In 1946, on notice and hearing, the defendant ordered and adjudged that this license be revoked. The present case is to review that order.

The court assumed at the outset that the scope of review was limited to the inquiry as to whether the board's jurisdiction has been exceeded, its discretion abused or its authority regularly pursued. The practice of chiropractic, said the court, is recognized and authorized by law. We must therefore accept such practice as a lawful occupation and as in the public interest. It may not be arbitrarily limited or discriminated against, and its advocates may lawfully erect and operate buildings and facilities for the treatment, according to its tenets, of patients seeking its aid, subject only to the limitations set out in the law and to reasonable regulations under the police power. Such regulations must, however, bear relation to the public health or welfare and must apply to all persons alike. The sole authority for the board in the issuance and revocation of licenses is contained in the state statute. This statute provides, so far as we are here concerned, that it shall be unlawful to open or maintain any hospital or other institution for the treatment or care of the sick or injured without first having obtained a license therefor from the state board of health; that the board "shall issue licenses to such applicants furnishing satisfactory evidence of fitness to conduct and maintain such institution in accordance with the provisions of this act and the rules and regulations adopted by such board, and such license shall be signed by the president and attested by the secretary of said board and have the seal thereof affixed thereto" and that licenses may be refused or revoked for failure to comply with the requirements of this act and of the rules and regulations of the board. This statute, said the Supreme Court, provides only for the issuance of permanent licenses, which shall continue until revoked.

It is at once apparent, said the Supreme Court, that the instrument issued to the plaintiff was in no respect a compliance with the statute under which the board must act. By its very terms it was not a license as authorized by the statute but an unauthorized, temporary provisional permit issued "pending consideration of an application for a permanent license." It was not signed by the president of the board nor even issued under its apparent authority, it was not attested by the secretary of the board, it did not bear its seal and most important of all it was not conditioned on a compliance with "the provisions of this act and the rules and regulations adopted by such board." Rather it was conditioned on five stated prohibitions no one of which was either a provision of the statute or properly or in fact a rule or regulation of the board. These prohibitions, the court continued, bear no relation to the sanitary conditions or the adequacy of equipment of the sanitarium, no relation to the training, competence or qualification of its personnel and no relation to the public health, morals, welfare or security. They are not set up as rules or standards for chiropractic sanitariums generally but are arbitrary and discriminatory restrictions against the applicant alone.

There is not a sentence in the issued license which follows the statute on which it is based. Instead of pursuing its statutory authority, the state board of health attempted to usurp the function of the legislature and set up a law of its own. However, the Supreme Court continued, the very fact that the board issued authority for the opening and operating of the sanitarium constitutes a finding of proper application for a license and satisfactory evidence of fitness to conduct and maintain the sanitarium. Such finding was a legal prerogative of the board and on such finding the board was legally obligated to issue a proper license in place of the one actually issued. Assuming that as done which should have been done, to wit the actual issuance of a proper license, and that such license was subject to revocation as provided by the statute, the revocation here ordered was of a certainty not in regular pursuit of authority. In the notice of hearing to revoke license upon which the hearing was based plaintiff was notified that the grounds of the revocation charged were that surgery had been performed, that drugs and medicines had been administered, that contagious and infectious diseases had been admitted and treated and that the name "hospital" had been used in describing or designating the institution. There was no charge that the licensee authorized or by negligence permitted surgery to be performed or drugs or medicine to be administered by persons or under conditions prohibited by law or regulation or that licensee violated any law or regulation in the admittance or segregation or treatment of contagious, infectious diseases or in the use of the word "hospital." The violation of void conditions could not justify revocation.

Accordingly, the Supreme Court held that the attempted revocation of license by the board was void and that the board should have issued a license in accordance with the law under which it acted. The judgment in favor of the board was therefore reversed.—*Spears Free Clinic & Hospital for Poor Children, Inc. v. State Board of Health, 220 P. (2d) 872 (Colo., 1950).*

Malpractice: Standards Applicable to Drugless Healers.—This was an action for damages alleged to have arisen out of the sanipractic treatment given to the plaintiff by the defendant. From a judgment in the trial court in favor of the defendant notwithstanding a verdict for the plaintiff, the plaintiff appealed to the Supreme Court of Washington.

The plaintiff had been informed by her physician that she had diabetes. She was averse to the administration of insulin, however, so she consulted the defendant, who informed her that by his method of treatment of diabetes neither insulin nor other drugs were used. There is evidence in the record from which the jury could have concluded that the plaintiff lost weight, had intermittent swelling of the ankles, a numbness of the limbs, impediment in vision and general physical weakness and had become irritable. After taking 41 treatments the plaintiff became alarmed, ceased taking them and entered a hospital. After a period of hospitalization and insulin therapy, the condition of the plaintiff improved to such an extent as to enable her to live a comparatively normal life.

We gather from the remarks of the trial judge, said the Supreme Court, that he considered a licensed sanipractor when operating within his school of treatment should be governed by the same rules applicable to a physician. The analogy does not apply to a drugless healer because he is restricted by statute to that which is permitted under the license issued to him. This is not a case where it can be said that the defendant was negligent in the performance of that which he undertook to accomplish. He knew the plaintiff had diabetes. It was not what he prescribed or instructed the plaintiff to do that created a foundation for legal liability. His fault, said the Supreme Court, lay in the fact that his method of treatment did not supply the pancreas deficiency necessary to retard the progress of the ailment with which the plaintiff was suffering. There was evidence before the jury sufficient to support a finding that the defendant knew or should have known, or discovered, that his method of treatment for diabetes was not of a character productive of reasonable success. When such a situation arises, concluded the Supreme Court, it then becomes the duty of a drugless healer to cease and desist from treating the patient and to advise the patient to seek other relief. Accordingly the judgment of the trial court in favor of the defendant was reversed and judgment in favor of the plaintiff was ordered.—*Carney et ux. v. Lydon et ux., 220 P. (2d) 894 (Wash., 1950).*

CURRENT MEDICAL LITERATURE

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1939 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

40:325-484 (Sept.) 1950

Myocardial Infarction Simulating Angina Pectoris. I. Stein.—p. 325.

*Myocarditis in Poliomyelitis. D. M. Spain, V. A. Bradess and V. Parsonnet —p. 336.

*Active Rheumatic Carditis in Patients over 40 Years of Age. F. Wroblewski and W. J. Messinger.—p. 345.

Spontaneous Rupture of Papillary Muscle: Clinical Syndrome. H. Schwartz and F. R. Canelli.—p. 354.

*Air Travel and the Cardiac Patient: Analysis of Relevant Experimental and Empirical Data. S. H. May.—p. 363.

Effect of L-Nor-Epinephrine upon Corpuscular Volume and Hematocrit. G. C. Sutton, A. Kappert, A. Reale and others.—p. 369.

Action of Nor-Epinephrine and of Epinephrine on Ventricular Rate of Heart Block. M. H. Nathanson and H. Miller.—p. 374.

Prolonged Study of Oral Veratrum Viride in Treatment of Essential Hypertension. J. D. McNair, G. C. Griffith and S. R. Elek.—p. 382.

Abnormal Ballistocardiographic Patterns in Cardiovascular Disease as Recorded with Low-Frequency, Critically-Damped Ballistocardiograph. J. A. L. Mathers, J. L. Nickerson, T. C. Fleming and M. C. Patterson. —p. 390.

Experimental Cholesterol Arteriosclerosis: II. Changes Produced in Golden Hamsters and in Guinea Pigs. R. Altschul.—p. 401.

Electrokymographic Studies of Abnormal Left Ventricular Pulsations. J. B. Schwedel, P. Samet and H. Mednick.—p. 410.

Electrokymographic Studies of Relation Between Electrical and Mechanical Events of Cardiac Cycle in Wolff-Parkinson-White Syndrome. P. Samet, H. Mednick and J. B. Schwedel.—p. 430.

Prominent R Wave and Shallow S Wave in Lead V_1 as Result of Lateral Myocardial Infarction. L. Levy II, H. J. Jacobs, H. P. Chastant and H. B. Strauss.—p. 447.

Electrocardiographic Diagnosis of Combined Left and Right Ventricular Strain. R. H. Rosenman, S. Krause, W. Hwang and L. N. Katz. —p. 453.

Explanation of Wolff-Parkinson-White Syndrome. B. Kisch.—p. 466.

Myocarditis in Poliomyelitis.—Spain and his associates point out that little is known about the incidence and degree of involvement of the myocardium during poliomyelitis and that the clinical significance of this myocarditis is not too well established. They studied the hearts of 14 of 16 patients who died from poliomyelitis at Grasslands Hospital in Westchester County during 1947 to 1949, inclusive. Sections of myocardium were taken from all parts of the heart. Spinal cord and brain were examined in all cases. Microscopic changes of myocarditis were present in 12 of the 14 patients. The alterations varied considerably from one case to another and in the same case from section to section. The histological findings correlated closely with the duration of illness, but the severity of myocarditis could not be correlated with the clinical type of poliomyelitis. The heart in which there were obvious gross findings of myocardial involvement was that of the only patient who during life showed a possible sign of myocarditis. He had a rapid pulse, despite the fact that his temperature had dropped to near normal. The terminal episode was also suggestive of some degree of cardiac failure. The authors believe that myocarditis is etiologically related to the poliomyelitis group of viruses, because of the close correlation between the histological picture in the myocardium and the duration of illness and the presence of focal myocardial necrosis and nerve lesions in the myocardium. They cite other reasons for favoring the etiological role of the poliomyelitis virus but admit that the virus has never been isolated from the myocardium. They suggest that the myocardium be studied in experimentally produced poliomyelitis in monkeys and that isolation of the virus from the myocardium be tried.

Active Rheumatic Carditis in Patients over 40 Years of Age.—According to Wroblewski and Messinger, active rheumatic heart disease is generally unsuspected in patients over 40 years of age, unless the manifestations are classic. This disease was frequently seen in older patients at the hospital with which the authors are connected. These patients are, however, highly selected, since they were admitted only after protracted illness in general hospitals. The diagnosis of rheumatic heart disease had been made previously in only a few of these. The 34 cases with histological evidence of active rheumatic heart disease on which this report is based were selected from 1,930 autopsy protocols. The clinical records of these patients were studied to determine whether cardiac activity noted in the histological sections resulted in clinical manifestations and whether patients over 40 years of age who had postmortem histological evidence of rheumatic carditis, differed in clinical manifestations from patients in the younger age groups. The possibility of rheumatic heart disease was considered at one time or another during hospitalization in 12 of the 34 cases, while activity of the rheumatic process was suspected in seven of these 12 cases. Evidently, many of these clinical impressions were not sustained. A past history of rheumatic fever or rheumatic-like illness was obtained from 14 patients. The physical findings alone suggested heart disease in 27 cases. Of the 32 cases in which complete clinical data were available, 10 patients exhibited classic or obvious signs of clinical activity; 16 exhibited adequate signs, and in six, minimal or no manifestations were apparent. If the diagnosis of active rheumatic carditis had been considered seriously in spite of the age of the patient, a correct diagnosis could have been arrived at in most of them. Active rheumatic carditis should be considered more often in older patients. Unexplained fever and unusual responses to digitalis may be clues to such a diagnosis.

Air Travel and the Cardiac Patient.—According to May, there exist physiological, experimental and empirical data which suggest the existence of a factor in the human body which increases tolerance to oxygen want in the aged and in those with cardiac disease. It seems likely that the alerted adjustor mechanism of the carotid and the aortic nerve structures plays a greater role in the emergency of oxygen want. Some of the mechanisms which participate in the adjustment of the body to high altitude, besides the well known acclimatization by polycythemia to altitude, are, according to Wiggers, increased cardiac output and vital capacity, a slight shift of the pH of the blood and an increased capacity of the blood to fix and use oxygen. There is also evidence that the coronary vessels dilate. The possibility of testing patients with cardiac disease under low oxygen pressures is regarded by the author as a strong argument for the high altitude tolerance of these patients. The collective experience of the airlines as well as the crucial experiment of the air evacuation of the sick and wounded from combat zones during the recent war seem to corroborate this view. The author presents three case histories to illustrate that patients with heart ailments tolerate air travel quite well and concludes that there is no valid objection to travel in modern air vehicles for patients with heart disease.

Physiological Disposition of Diodoquin, Vioform, and Chiniofon in Rabbit as Determined with Radioiodine. W. T. Haskins, G. W. Luttermoser and F. J. Brady.—p. 599.
Effectiveness of Bismuthoxy *p*-N-Glycolylarsanilate (Milibis®) in Treatment of Intestinal Amebiasis. D. A. Berberian, E. W. Dennis and C. A. Pipkin.—p. 613.
Trial of Enteric-Coated Camoquin in Intestinal Amebiasis. M. T. Hoekenga and Q. Gonzalo Maximo.—p. 625.
Effect of Rice Powder on Growth of Cultures of Endamoeba Histolytica. C. L. Spingarn and M. H. Edelman.—p. 629.
Effect of X-Ray upon Growth and Infectivity of Endamoeba Histolytica. E. H. Sadun, J. N. Ané, F. W. Fuller and R. Lewis.—p. 635.
Simplified Casein Hydrolysate-Serum Medium for Cultivation of Trichomonas Vaginalis. J. J. Lash.—p. 641.
Laboratory Infection with Leishmania Donovani: Case Report. L. L. Terry, J. L. Lewis Jr. and S. M. Sessoms.—p. 643.
Observations on Recession of Malaria in Area of Southwestern Georgia. M. H. Goodwin Jr.—p. 651.
Heretofore Unreported Agglutinable Human Blood Factor and Its Possible Relationship to Blackwater Fever. D. C. A. Butts.—p. 663.
*Progress in Treatment of Trachoma with Chloromycetin (Chloramphenicol). M. J. Pijoan, E. H. Payne and J. Duncan.—p. 677.
Observations on Experimental Transmission of Japanese Encephalitis by Mosquitoes. H. S. Hurlbut and J. I. Thomas.—p. 683.
Japanese B Encephalitis: Complete Review of Experience on Okinawa 1945-1949. W. D. Tigertt, W. M. Hammon, T. O. Berge and others. —p. 689.
Geographical Distribution of Immunity to Yellow Fever Among Primates of Brazil. H. W. Kumm and H. W. Laemmert Jr.—p. 733.
Study of Concentration of Yellow Fever Virus which Will Infect Certain Species of Aedes Mosquitoes. H. W. Kumm and H. W. Laemmert Jr. —p. 749.
Diabetes Mellitus and Pylephlebitic Abscess of Liver Resulting from Schistosoma Mansoni Infestation. M. Seife and J. R. Lisa.—p. 769.
Seventeen Cases of Poisoning Due to Ingestion of Eel, Gymnothorax Flavimarginatus. C. T. Khlentzos.—p. 785.

Chloramphenicol in Treatment of Trachoma.—Pijoan and his co-workers report on cases of trachoma characterized by an acute onset of conjunctival inflammation, dense infiltration and papillary hypertrophy. In the early stages' there existed in these patients a superficial inflammation of the cornea, particularly of the upper limbus region, some swelling of the lids and increased lacrimation. There was a follicular hypertrophy of the upper tarsal conjunctiva. Pannus was noted in all cases, and capillary loops were observed within the matrix of this structure. Corneal and conjunctival cicatrization was present in the later stages, and early deformities, such as cicatricial entropion were noted in some of the patients. Eight children and six adults were treated with chloramphenicol. The diagnosis was based on the slit lamp and biomicroscope examination, in addition to bacteriologic and physical examinations. Chloramphenicol was administered orally, 3 Gm. being given in divided doses at three-hour intervals for the first 24 hours, after which 250 mg. were given every three hours for at least four days. Most of the photophobia and lacrimation was materially reduced within 24 hours, and there was a reduction of approximately 85 per cent in opacities and inflammation within the next few days. The patients were hospitalized with bed rest in partly darkened rooms for four days and were on a regular diet. They were protected from dust and wind. Examination at the termination of treatment showed only one patient in whom further therapy appeared necessary. The authors feel that the benefits will probably be permanent, because there was no evidence of relapse over a period of three months.

Ainhum (Dactylolysis Spontanea): Review of 10 Cases. D. C. Hucherson.—p. 312.

Cervical Arteriovenous Anastomosis for Mental Retardation.—McKhann and his associates describe an operation to increase the arterial blood supply to the cortex of the cerebrum. This involves the production of an arteriovenous anastomosis between one of the carotid arteries and the internal jugular vein, with ligation of the jugular vein proximad to the anastomosis. It was thought that there might be in some conditions viable brain cells enmeshed in a gliotic process and that the function of these cells could be improved by increasing the blood supply to the brain. The operation was performed in 125 patients. Recently, the external carotid artery was used rather than the common carotid artery. The original common carotid-internal jugular anastomosis was done in 52 children and 26 adults, while the other patients were subjected to the later procedure. Children with developmental anomalies were excluded from this treatment, because it was reasoned that the operation could be successful only if there had been normal development with subsequent injury. Children with birth injury, birth anoxia, encephalitis, kernicterus, cortical atrophy secondary to subdural hemorrhage and lesions from meningitis and from hyperpyrexia were selected for treatment. The adults operated on had convulsive disorders secondary to organic change, idiopathic epilepsy, arteriosclerosis, cerebrovascular complications, sequelae of cerebral emboli and thrombosis not secondary to arterioslerosis. It was found that the carotid-jugular anastomosis increases cerebral blood flow and that it may bring about a revascularization of the brain. Anastomosis between the external carotid artery and the internal jugular vein, within limits of a 3.5 to 4.0 mm. stoma, proved to be reasonably safe. About 35 per cent of the children and a small percentage of adults have shown postoperative benefit. The procedure is still in the trial stage and should be considered as representing a new approach to the problem rather than an aceptable and complete solution.

Adrenal Cortex and Postoperative Retention of Salt and Water.—Hardy points out that patients subjected to major surgical procedures frequently retain significant amounts of infused sodium chloride and glucose solutions during the immediate postoperative period. He felt that this retention of salt and water might be related to the activity of the adrenal cortex after the trauma of anesthesia and operation. In the absence of facilities for the fractionation of urinary corticoids, he selected the total eosinophil count as a measure of adrenocortical function. Infusions of 2,000 cc. of 5 per cent glucose in water and of 1,000 cc of 5 per cent glucose in 0 85 per cent sodium chloride solution were administered daily for three days following operation in five patients who had undergone partial colon resection, one a vagotomy and one a hemorrhoidectomy The urinary volume and the total output (urine plus gastrointestinal suction) were correlated with the total eosinophil counts, and it was found that the curves could be almost superimposed In a second group of three patients, one of whom underwent gastric resection, one resection of the right colon and one combined abdominoperineal resection 750 cc of a 5 per cent dextrose solution were administered in each of the first four six-hour periods postoperatively, and rates of urinary excretion of water, sodium, potassium and chloride were measured and correlated with the total eosinophil counts in each period When adrenocortical function was maximal, as indicated by a profound fall in the total eosinophil count, there was a decreased rate of excretion of sodium, water and chloride, with an increased rate of excretion of potassium The rates of excretion were identical with results obtained following the administration of desoxycorticosterone The author discusses a number of factors which might affect the postoperative excretion of salt and water The vigor of eosinophil response to trauma may be in some way related to the vitality of the patient He draws attention to the diminished volume of fluids secreted into the intestinal tract during the first 24 hours postoperatively This may represent another manifestation of a profound generalized derangement in the membrane permeability

Hereditary Spherocytic Anemia in the Negro.—Butterworth and co workers studied 12 persons representing four generations of a Negro family, two of whom, both women, appeared to have typical cases of hereditary spherocytic anemia Splenectomy was performed on one The blood values returned to normal, and the patient remained completely well The second patient never had a hemolytic crisis, although reticulocytosis and the large size of the spleen indicated that the disease was active Five persons were normal The remaining five had microspherocytosis and an increased red cell fragility but were completely asymptomatic and appeared in good health They were considered carriers of hereditary spherocytic anemia This disease has always been thought to be transmitted as a simple *mendelian dominant factor* With regard to the genetic mechanism involved the presence of three recognizable categories—patients, carriers and normals—indicates at once that a simple single gene, dominant recessive relation is not the explanation The suggestion is made that spherocytic anemia in the Negro is due to multiple factors The high incidence of the disease in females is again pointed out

Paroxysmal Nocturnal Hemoglobinuria—Crosby and Dameshek studied the mechanics of hemolysis in the blood of six patients with paroxysmal nocturnal hemoglobinuria, a rare hemolytic anemia of obscure origin, characterized by a defect of the erythrocytes, which makes them susceptible to hemolysis by a normal plasma or serum factor Results showed that the hemolytic reaction does not involve a complement antibody reaction, but is rather an enzyme-like reaction that is related to the coagulation mechanism of the blood Evidence suggests that the heat-labile hemolytic factor in paroxysmal nocturnal hemoglobinuria if not identical with the serum coagulation accelerator, resembles it in many aspects The hemolytic factor is present in plasma as an inert precursor which is activated by thrombin Bishydroxycoumarin (dicumarol®) inhibited hemolysis in a patient with paroxysmal nocturnal hemoglobinuria Therapeutically, the drug was disappointing It did not reduce the hemolytic precursor and did *not prevent* hemolytic crises, but its use was not dangerous, suggesting that it may be of value during crises of this disease when thrombosis threatens Dilute heparin facilitated the activation of the hemolytic enzyme by thrombin The use of heparin in paroxysmal nocturnal hemoglobinuria may be dangerous Lysis of paroxysmal nocturnal hemoglobinuria of cells by a substance related to the clotting mechanism offers a new approach to the study of the coagulation problem

Hypoxia and Ascorbic Acid Excretion—Krasno and his associates observed that exposure of human subjects to hypoxia in an altitude chamber appeared to alter the metabolism of ascorbic acid They found that *when subjects* were receiving 91 mg of ascorbic acid daily and were exposed to an altitude of 18,000 feet without oxygen supplementation, there occurred a gradual depletion of ascorbic acid Evidence indicates that the depletion was due to increased utilization When persons were receiving 141 mg of ascorbic acid daily and were exposed three times a week to an altitude of 35,000 feet while breathing 100 per cent oxygen, a hyperexcretion of ascorbic acid occurred during four weeks of exposure At this level of intake of ascorgic acid, it is unlikely that any tissue deficiency will occur with time In view of the role that ascorbic acid plays in cellular oxidation-reduction reactions, its presence normally in a relatively high concentration in the adrenals and the observation that the vitamin may be depleted by repeated exposure to hypoxia, which also depletes body base, it is suggested that liberal quantities of fruit or fruit juices be supplied in the diet of persons who may be subjected to exposure to a discontinuous or continuous hypoxia, or to hyperventilation

Effects of Acceleration—Rosenfeld and Lombard are concerned with the effects of negative acceleration (negative gravity), by which they mean the acceleration that acts *in the head* to heart direction and that results in the force of inertia tending to throw the blood mass and organs toward the head The study of comparative physiology reveals wide *variations* in response of the various members of the mammalian family The authors studied 28 animals, including 10 goats, 10 dogs, 5 monkeys and 3 rabbits When the data obtained were compared with those available for man, it was found that the monkey and the dog respond in a manner that most closely parallels the reflex cardiovascular response shown by man during the action of negative gravity It is believed that the animal or person experiences the most harmful insult to cerebral circulation at the termination of the acceleration Factors that tend to maintain minute cardiac output as well as factors preventing generalized vasodilatation should be investigated for possibilities of offering greater tolerance to negative acceleration It seems likely that the symptoms experienced by pilots exposed to negative gravity may be attributed to two phenomena (1) the increase in intravascular and extravascular cephalic pressure and (2) the stagnation of cerebral flow The former produces the feeling of extreme fulness of the head while the latter is probably responsible for mental confusion, and loss of consciousness The possibility of a central type of syncope from stimulation of the carotid sinus cannot be overlooked

Treatment of Scarlet Fever.—Weinstein and Potsubay treated 255 patients with scarlet fever by three different regimens The three types of treatment were a single intramuscular injection of 20 to 60 cc of gamma globulin, penicillin in a dose of 15,000 units given intramuscularly every three hours (120,000 units daily) for 10 days and so-called symptomatic treatment, consisting of bed rest and throat irrigations Gamma globulin was observed to cause rapid fading of the rash but had no effect on the streptococci in the pharynx, allowed the carrier state to persist as long as it did in untreated patients and had little, if any, effect on the development of suppurative complications or such nonsuppurative sequelae as rheumatic fever Penicillin appeared to be the agent of choice in the treatment of scarlet fever, because it caused rapid disappearance of the local focus of infection, eradicated Streptococcus pyogenes from the pharynx speedily assured eradication of the carrier state and significantly decreased the incidence of serious suppurative complications The problem of the occurrence of rheumatic fever and of glomerular nephritis following treatment of the initial streptococcic infection will be discussed in a later paper In the group of patients given symptomatic treatment the course of the disease was more or less typical There was a relatively slow recovery at the site of streptococcic invasion, frequent persistence of the organism for a period beyond the isolation time and the occurrence of local and distant bacterial and nonbacterial complications

Aureomycin in Pertussis—Miller and Ross treated with aureomycin six children with pertussis who were between the ages of 5 weeks and 3 years Doses of 350 mg per kilogram of body weight were given every 24 hours for periods of eight to 10 days Hyperimmune serum was administered before the use of aureomycin in three cases, and, in one of these, streptomycin was given intramuscularly for an 18 hour period just preceding the start of aureomycin therapy All the patients manifested severe types of the disease Improvement in these patients after institution of aureomycin treatment was gradual and steady Patients who were cyanotic and vomiting showed the greatest change These manifestations usually cleared by the third to fifth day Elevated temperatures, when present, subsided in this interval as well Paroxysms of coughing persisted for a longer time but with steadily diminishing frequency The patients were free of this symptom by the seventh to the tenth day after institution of the treatment Convalescence after the initial period of improvement was uneventful Despite poor prognosis, almost complete recovery occurred in less than two weeks in all the patients after the institution of aureomycin treatment Although some of the patients received other therapy, the improvement in all occurred following aureomycin therapy alone The uniformity of the recovery following aureomycin therapy is the best evidence for the effectiveness of the drug, although the small number of cases reported does not permit precise evaluation or adequate comparison with other methods of treatment

Anticoagulant Therapy.—The crux of anticoagulant therapy, according to Jaques, is careful control of the drug so as to steer an even course between the dangers of thrombosis and those of hemorrhage Of the two anticoagulants in general use, heparin acts directly on the blood It is ineffective by mouth of 1,000 cc. of 5 per cent glucose in 0.85 per cent sodium chloride solution were administered daily for three days following operation in five patients who had undergone partial colon resection, one a vagotomy and one a hemorrhoidectomy. The urinary volume and the total output (urine plus gastrointestinal suction) were correlated with the total eosinophil counts, and it was found that the curves could be almost superimposed. In a second group of three patients, one of whom underwent gastric resection, one resection of the right colon and one combined abdominoperineal resection, 750 cc. of a 5 per cent dextrose solution were administered in each of the first four six-hour periods postoperatively, and rates of urinary excretion of water, sodium, potassium and chloride were measured and correlated with the total eosinophil counts in each period. When adrenocortical function was maximal, as indicated by a profound fall in the total eosinophil count, there was a decreased rate of excretion of sodium, water and chloride, with an increased rate of excretion of potassium. The rates of excretion were identical with results obtained following the administration of desoxycorticosterone. The author discusses a number of factors which might affect the postoperative excretion of salt and water. The vigor of eosinophil response to trauma may be in some way related to the vitality of the patient. He draws attention to the diminished volume of fluids secreted into the intestinal tract during the first 24 hours postoperatively. This may represent another manifestation of a profound generalized derangement in the membrane permeability.

Hereditary Spherocytic Anemia in the Negro.—Butterworth and co-workers studied 12 persons representing four generations of a Negro family, two of whom, both women, appeared to have typical cases of hereditary spherocytic anemia. Splenectomy was performed on one. The blood values returned to normal, and the patient remained completely well. The second patient never had a hemolytic crisis, although reticulocytosis and the large size of the spleen indicated that the disease was active. Five persons were normal. The remaining five had microspherocytosis and an increased red cell fragility but were completely asymptomatic and appeared in good health. They were considered carriers of hereditary spherocytic anemia. This disease has always been thought to be transmitted as a simple mendelian dominant factor. With regard to the genetic mechanism involved, the presence of three recognizable categories—patients, carriers and normals—indicates at once that a simple single-gene, dominant-recessive relation is not the explanation. The suggestion is made that spherocytic anemia in the Negro is due to multiple factors. The high incidence of the disease in females is again pointed out.

Paroxysmal Nocturnal Hemoglobinuria.—Crosby and Dameshek studied the mechanics of hemolysis in the blood of six patients with paroxysmal nocturnal hemoglobinuria, a rare hemolytic anemia of obscure origin, characterized by a defect of the erythrocytes, which makes them susceptible to hemolysis by a normal plasma or serum factor. Results showed that the hemolytic reaction does not involve a complement-antibody reaction, but is rather an enzyme-like reaction that is related to the coagulation mechanism of the blood. Evidence suggests that the heat-labile hemolytic factor in paroxysmal nocturnal hemoglobinuria if not identical with the serum coagulation accelerator, resembles it in many aspects. The hemolytic factor is present in plasma as an inert precursor which is activated by thrombin. Bishydroxycoumarin (dicumarol®) inhibited hemolysis in a patient with paroxysmal nocturnal hemoglobinuria. Therapeutically, the drug was disappointing. It did not reduce the hemolytic precursor and did not prevent hemolytic crises, but its use was not dangerous, suggesting that it may be of value during crises of this disease when thrombosis threatens. Dilute heparin facilitated the activation of the hemolytic enzyme by thrombin. The use of heparin in paroxysmal nocturnal hemoglobinuria may be dangerous. Lysis of paroxysmal nocturnal hemoglobinuria of cells by a substance related to the clotting mechanism offers a new approach to the study of the coagulation problem.

Hypoxia and Ascorbic Acid Excretion.—Krasno and his associates observed that exposure of human subjects to hypoxia in an altitude chamber appeared to alter the metabolism of ascorbic acid. They found that when subjects were receiving 91 mg. of ascorbic acid daily and were exposed to an altitude of 18,000 feet without oxygen supplementation, there occurred a gradual depletion of ascorbic acid. Evidence indicates that the depletion was due to increased utilization. When persons were receiving 141 mg. of ascorbic acid daily and were exposed three times a week to an altitude of 35,000 feet while breathing 100 per cent oxygen, a hyperexcretion of ascorbic acid occurred during four weeks of exposure. At this level of intake of ascorgic acid, it is unlikely that any tissue deficiency will occur with time. In view of the role that ascorbic acid plays in cellular oxidation-reduction reactions, its presence normally in a relatively high concentration in the adrenals and the observation that the vitamin may be depleted by repeated exposure to hypoxia, which also depletes body base, it is suggested that liberal quantities of fruit or fruit juices be supplied in the diet of persons who may be subjected to exposure to a discontinuous or continuous hypoxia, or to hyperventilation.

Effects of Acceleration.—Rosenfeld and Lombard are concerned with the effects of negative acceleration (negative gravity), by which they mean the acceleration that acts in the head-to-heart direction and that results in the force of inertia tending to throw the blood mass and organs toward the head. The study of comparative physiology reveals wide variations in response of the various members of the mammalian family The authors studied 28 animals, including 10 goats, 10 dogs, 5 monkeys and 3 rabbits When the data obtained were compared with those available for man, it was found that the monkey and the dog respond in a manner that most closely parallels the reflex cardiovascular response shown by man during the action of negative gravity It is believed that the animal or person experiences the most harmful insult to cerebral circulation at the termination of the acceleration Factors that tend to maintain minute cardiac output as well as factors preventing generalized vasodilatation should be investigated for possibilities of offering greater tolerance to negative acceleration It seems likely that the symptoms experienced by pilots exposed to negative gravity may be attributed to two phenomena (1) the increase in intravascular and extravascular cephalic pressure and (2) the stagnation of cerebral flow The former produces the feeling of extreme fulness of the head, while the latter is probably responsible for, mental confusion, and loss of consciousness The possibility of a central type of syncope from stimulation of the carotid sinus cannot be overlooked

Treatment of Scarlet Fever.—Weinstein and Potsubay treated 255 patients with scarlet fever by three different regimens The three types of treatment were a single intramuscular injection of 20 to 60 cc of gamma globulin, penicillin in a dose of 15,000 units given intramuscularly every three hours (120,000 units daily) for 10 days and so-called symptomatic treatment, consisting of bed rest and throat irrigations Gamma globulin was observed to cause rapid fading of the rash but had no effect on the streptococci in the pharynx, allowed the carrier state to persist as long as it did in untreated patients and had little, if any, effect on the development of suppurative complications or such nonsuppurative sequelae as rheumatic fever Penicillin appeared to be the agent of choice in the treatment of scarlet fever, because it caused rapid disappearance of the local focus of infection, eradicated Streptococcus pyogenes from the pharynx speedily assured eradication of the carrier state and significantly decreased the incidence of serious suppurative complications The problem of the occurrence of rheumatic fever and of glomerular nephritis following treatment of the initial streptococcic infection will be discussed in a later paper In the group of patients given symptomatic treatment the course of the disease was more or less typical There was a relatively slow recovery at the site of streptococcic invasion, frequent persistence of the organism for a period beyond the isolation time and the occurrence of local and distant bacterial and nonbacterial complications

Aureomycin in Pertussis.—Miller and Ross treated with aureomycin six children with pertussis who were between the ages of 5 weeks and 3 years Doses of 350 mg per kilogram of body weight were given every 24 hours for periods of eight to 10 days Hyperimmune serum was administered before the use of aureomycin in three cases, and, in one of these, streptomycin was given intramuscularly for an 18 hour period just preceding the start of aureomycin therapy All the patients manifested severe types of the disease Improvement in these patients after institution of aureomycin treatment was gradual and steady Patients who were cyanotic and vomiting showed the greatest change These manifestations usually cleared by the third to fifth day Elevated temperatures, when present, subsided in this interval as well Paroxysms of coughing persisted for a longer time but with steadily diminishing frequency. The patients were free of this symptom by the seventh to the tenth day after institution of the treatment Convalescence after the initial period of improvement was uneventful Despite poor prognosis, almost complete recovery occurred in less than two weeks in all the patients after the institution of aureomycin treatment Although some of the patients received other therapy, the improvement in all occurred following aureomycin therapy alone The uniformity of the recovery following aureomycin therapy is the best evidence for the effectiveness of the drug, although the small number of cases reported does not permit precise evaluation or adequate comparison with other methods of treatment

Anticoagulant Therapy.—The crux of anticoagulant therapy, according to Jaques, is careful control of the drug so as to steer an even course between the dangers of thrombosis and those of hemorrhage Of the two anticoagulants in general use, heparin acts directly on the blood It is ineffective by mouth and must be given parenterally It acts immediately, and recovery is rapid This means that control of anticoagulant therapy using heparin is relatively simple The clotting time will rapidly return to normal when administration is stopped When a great excess of heparin has been administered through error, an antidote is available in the form of protamine Bishydroxycoumarin (dicumarol®) acts by interfering with the formation of thrombin by the liver It increases the prothrombin time but has no effect on the clotting time The latent period is about 24 to 40 hours It is long acting After cessation of treatment with this drug the prothrombin time may remain prolonged for as long as 10 days Hence, control is not as easy if overdoses of the drug are given inadvertently The antidote for overdosage is fresh blood Large doses of vitamin K neutralize the action of bishyroxycoumarin experimentally but are of less value clinically as an antidote The author discusses the measurement of the degree of hypocoagulability produced by these drugs and the maintenance of levels of the drugs in the body sufficient to guarantee satisfactory hypocoagulability He stresses that during treatment with heparin the clotting time must be determined and during treatment with bishydroxycoumarin the prothrombin time must be watched

Parenteral Potassium Therapy in Surgical Patients—Lowe and co-workers studied the serum chloride concentration in five surgical patients, two infants aged 21 months and 7 months with intussusception and three children, two with perforated appendix and peritonitis Material removed by gastrointestinal suction and the urine were analyzed for sodium, chloride, potassium and nitrogen One of the two children with a perforated appendix received sodium chloride and dextrose, the other a similar regimen, to which potassium was added Alimentation was entirely by vein Both children had approximately the same water intake Results supplemented previous observations by other investigators that following surgical intervention patients may have a low serum chloride concentration These patients show the effects of fasting, dehydration and potassium depletion owing to an alarm reaction or to alkalosis from loss of gastric chloride Administration of isotonic sodium chloride solution may be ineffective in accomplishing extracellular repair, because sodium and water go to the dehydrated and potassium depleted cells and the chloride is excreted More effective physiological hydration of both fluid compartments of the body (chloride being conserved by the kidneys and sodium tending to stay in its proper extracellular position) may be obtained by a decrease in the ratio of sodium to water and addition of potassium Similar conservation of urinary chloride and elevation in serum chloride has been noted following potassium therapy in patients with low serum chloride concentrations associated with ulcerative colitis, where excessive loss of potassium and chloride in the urine suggests a similar alarm reaction

Neurological Lesions in Newborn Infants—Keith and Norval report that 57 (1 3 per cent) of 4,464 infants born in St Mary's Hospital in Rochester, Minn, in the course of one year, had lesions that affected the nervous system primarily and that were evident during the neonatal period There were only five among the 57 infants who had plainly difficult births It seems reasonable to conclude that difficulties during delivery *had comparatively little to do with persistent neurological* abnormalities in most of the infants who survived A survey was made of the condition of infants born in the same hospital during two and a half years to determine the relation of prolonged labor, asphyxia and delayed respiration to the occurrence of trauma and, thereby, the relation to neurological lesions of the infant Prolonged labor appeared to increase the risk of intracranial injury and death of the infant However, *if the infants survived, there was little or no abnorality in subsequent* development and no increase in neurological disturbances, at least during the first few years of life More children had convulsive disorder in the "normal" or control group than in the group of those subjected to prolonged delivery The same was true among the infants who were asphyxiated, that is there were more who had convulsive disorder in the control group than among those who were asphyxiated There were more deaths and more abnormal infants among those who were asphyxiated, but these included many premature infants, of whom many were not viable If the infants survived the neonatal period, they developed normally, or at least no more abnormalities were noted among those who were asphyxiated than among the controls Anoxia caused by delay in respiration did not have a serious prognosis in those infants who survived the neonatal period Even a delay of 11 to 15 minutes, while fatal in two instances, did not appear to cause any abnormality, at least during the first four years of life, in the infants who survived

Mercurial Diuretics in Ambulatory Patients—Stroud and his associates stress the advantages of oral over parenteral administration of diuretics They used mercurital, a combination of mersalyl acid and theobromine calcium They administered this preparation orally for one to eight months to 22 ambulatory patients, who previously required one or two weekly injections of a parenteral mercurial diuretic for the control of congestive heart failure The orally administered diuretic was found to be as effective as the parenterally administered preparations in the prevention and control of congestive failure in ambulatory patients when given in dosage of one to three tablets daily Although gastric irritation and nausea appeared to be minimized, this drug, like other preparations orally administered, caused soreness of the gums, abdominal cramps and diarrhea in certain patients. These untoward effects occurred in six patients in the present series, all of whom were taking two or more tablets daily. They prohibited further use of the drug in four of these patients, and they were adequately controlled in the remainder of the patients by temporary withdrawal of the drug, reduction of dosage and improvement in oral hygiene. The oral use of this diuretic appears preferable to the parenteral administration of mercurial diuretics for ambulatory patients in the absence of individual susceptibility to complicating stomatitis and intestinal disorders.

Music in Hospital and Operating Room.—Pickrell and his co-workers report on the use of music at Duke Hospital. Facilities for radio reception are provided for patients in their rooms or wards. The authors believed that music might be even more beneficial to patients who are being operated on under local, regional or spinal anesthesia. The comfort and composure of patients was apparent immediately, and their minds were diverted and occupied by the music rather than by the thought of the operation. Since the most suitable music could not always be obtained from the radio and because of the annoyance of static interference from x-ray and other hospital apparatus, record players were used. The authors stress the importance of music as a psychotherapeutic factor in the treatment of all patients, particularly of surgical patients and of children. Music that is slow, restful and suggestive of calm and sleep is usually most desired by patients. Hymns, spirituals and martial music increased the emotional tension in some patients and were the least acceptable. Cushioned earphones exclude all sounds from the operating room, thereby placing the patient, surgeon and assistants at comparative ease, since the possibility of erroneous interpretation of conversation or the development of harmful suspicion is eliminated. A radio-phonograph with automatic record changer supplies an almost continuous source of music or reading. Slow revolving unbreakable records are available with essentially unlimited selection of type of music.

Beryllium Granuloma of Nose.—Kazanjian and Joseph describe the case of a man who developed a granulomatous lesion on the dorsum of the nose following laceration by a fluorescent bulb. The wound failed to heal, and it appeared ragged and inflamed. A biopsy specimen revealed a granulomatous reaction suggestive of both sarcoid and of tuberculosis. The lesion was completely excised, with a generous margin of normal skin about it and replaced with a full thickness graft taken from behind the ear. Care was taken to suture the graft to the normal skin margin. Examination of the resected specimen disclosed granuloma of the beryllium type. The graft was completely successful. There was no evidence of recurrence several months later. Beryllium granuloma is best dealt with by wide excision, the wound being grafted or primarily reapproximated, depending on its location.

Intervertebral Disks.—Odell and co-workers removed one or more intervertebral disks in 455 patients for the relief of a low back pain and sciatica. Of these, 310 were followed by questionnaire. Satisfactory results were obtained in 277 patients (89.4 per cent) and poor in 33 patients (10.6 per cent). Relief of pain was complete in 136 patients (43.5 per cent). In 141 patients (45.4 per cent), there was slight intermittent pain that did not prevent their return to work. Spinal fusion was seldom done in this series. Myelography was not employed as a routine diagnostic procedure. The operative treatment of ruptured intervertebral disk is a satisfactory procedure when the patient is properly selected and the operation is performed by a surgeon who has learned to do it properly. The results in compensation cases are sufficiently good to warrant surgical treatment of patients with intractable low back and sciatic pain. Surgical intervention should not be advised for any of these patients until conservative treatment has been given a reasonable trial and has failed.

Panniculitis.—Jones and co-workers report the occurrence of panniculitis in three patients, one woman aged 52 and two newborn infants. Panniculitis is an inflammation of the panniculus adiposus. Its origin is undetermined. It was first described by Pfeifer in 1892, and 34 cases have been reported up to 1949. The authors' adult patient noted the appearance of nodules on her arms and legs in association with menstruation. The lesions broke down and underwent liquefaction necrosis, discharging a purulent, oily material after the patient was given a series of roentgen treatments to curb excessive menopausal bleeding. It seems possible that the radiation may have upset the hormonal balance and that this in turn changed the reaction in the fat tissue. The patient's course was progressively downhill, with new lesions appearing on the arms, abdomen, buttocks and thighs. Large pieces of necrotic tissue sloughed out of the affected areas. The patient died seven weeks after admission to the hospital. Necropsy showed fatty degeneration of the liver cells and necrosis. Fat necrosis of the newborn was observed in the two infants. The fever in the female infant was found to be due to an associated ear infection, while prolonged elevation of temperature and anemia in the male infant were apparently part of the fat tissue changes, since no secondary infection of the involved areas themselves or of other tissues was observed. The second infant underwent a severer type of change, with greater local disturbance, entailing more systemic reaction. The first infant's mother was a known diabetic, while fat embolism was suspected in the death of the mother of the second infant, although this was not confirmed by necropsy. A congenital abnormality of fat tissue enzymes may be the causative factor in cases of Weber-Christian disease in the newborn. Several authors advanced the hypothesis that some disturbance of the nutrition or of the metabolism of fat cells so changes the nature of normal fat that it acts as a foreign body, bringing about the inflammatory reaction and degenerative alterations characteristic of an invasion of foreign body giant cells.

Licorice Extract with Deoxycortone-Like Action.—According to Molhuysen and his associates, Revers reported from the Netherlands that many patients with peptic ulcer improved after taking a proprietary preparation that consisted of a mixture of succus liquiritiae, fructus anisi and ferrum reductum. The majority of the patients became symptom free within a short time. Roentgen examination revealed that sometimes a deep ulcer of the lesser curvature disappeared within three weeks. Edema developed in one out of every five patients treated; many complained of a headache, and some noticed shortness of breath and abdominal pain. It was ascertained that the edema-producing factor was either glycyrrhizin or some substance precipitated with it by acid. The effects observed were similar to those following injection of large doses of deoxycortone or of injection of pituitary adrenocorticotropic hormone (ACTH). Apparently succus liquiritiae and the purified product contained a substance similar in action to that of one of the two hormones. The substance was active when taken by mouth. The authors studied the urinary output of sodium, potassium and creatinine after the administration of the hormones and of succus liquiritiae. They emphasize, especially in elderly patients, the harmful effects of potassium loss on the myocardium, which is overburdened by the increased venous pressure and by the considerable rise in blood pressure. The occurrence of cardiac asthma in subjects using licorice in sweets or in drugs is thus explained. The effect of a licorice extract taken by mouth is similar to that of injection of large doses of deoxycortone, but it lasts longer. The blood pressure tends to remain elevated after discontinuance of the drug unless a salt-free diet is used. The retention of water and sodium chloride during treatment with deoxycortone, pituitary adrenocorticotropic hormone or succus liquiritiae is self limiting, in subjects with normal heart and kidneys, because the rise in venous pressure leads to an increase in cardiac output, which induces a saline diuresis. A patient with Addison's disease who did not respond to pituitary adrenocorticotropic hormone did not respond positively to succus liquiritiae. There was a slight negative response. A patient with rheumatoid arthritis who responded favorably to pituitary adrenocorticotropic hormone showed an insignificant improvement, or none, after the use of succus liquiritiae.

Increased Urinary Output of Arterenol and Epinephrine in Pheochromocytoma.—According to Engel and von Euler, epinephrine (adrenalin®) and other catechol derivatives, when administered to man, are partly excreted in the urine in a conjugated form. Since catechol derivatives may be extracted from urine and estimated quantitatively in a comparatively simple way (Euler and Hellner, 1950), it appeared that an increased formation and output of such substances could be used as basis for the diagnosis of pheochromocytoma. The authors cite two patients who showed a greatly increased arterenol-epinephrine output in the urine. In the first case, a tumor situated at the bifurcation of the abdominal aorta and weighing 48 Gm. was removed. Histological examination revealed a typical pheochromocytoma. In the second case a tumor weighing 20 Gm. was removed from the left suprarenal. The relative contents of the catechols in the two tumors were also borne out by paper chromatography. The proportions of arterenol and epinephrine in the urine were approximately the same as in the tumors.

Cortisone and Tuberculosis in Mice.—D'Arcy Hart and Rees produced in mice a chronic pulmonary tuberculous infection sufficiently stable to serve as a test infection. Intravenous injection of 0.0006 mg. dry weight of human type tubercle bacilli produced in mice an infection that was relatively nonprogressive over six to 12 weeks and was characterized during this period by small, discrete, predominantly proliferative, pulmonary lesions containing scanty tubercle bacilli. A daily dosage of 0.25-05 mg. of cortisone given subcutaneously for two to three weeks during the stable period of this chronic pulmonary infection greatly exacerbated the disease, with a resulting high mortality. The voluminous lungs now contained large coalescing necrotic lesions with great numbers of tubercle bacilli. The more acute type of tuberculous infection in the mouse, produced by intravenous injection of 0.06 mg. of bacilli, was also aggravated by 0.5 mg. daily of cortisone, given from the first until the ninth day of infection. The chronic infection test proved highly satisfactory as a method for demonstrating increased susceptibility to tuberculosis due to cortisone. The acute infection test was more difficult to interpret. The effect of cortisone on murine tuberculosis is not likely to be due to depression of allergy or of collagen formation. Although human tuberculosis differs considerably from the murine form, and the present dosage of cortisone was relatively high, these observations should be kept in mind since tuberculosis in man may possibly be similarly aggravated.

Aerosol Penicillin Therapy for Infant and Children P Karlberg, G Sterner and G Wallmark —p 263
*Human Hyperimmune Serum and Streptomycin for Treatment of Whooping Cough in Infants and Young Children I Hatz and C Burckhardt —p 274

Interrupted Penicillin Therapy in Suppurative Otitis —The interrupted administration of penicillin employed by Jersild and Kiørboe consists in giving only two doses each day, instead of giving it every three or four hours, as is customary with other clinics The individual doses for infants less than 1 year old were 60,000, for those between 1 and 5 years, 90,000, for those between 5 and 15 120,000 and for those over 15 years, 150 000 The authors treated 266 patients with 385 suppurating ears The otitis was a sequel of scarlet fever in about two thirds of the patients Hemolytic streptococci were the organisms most frequently demonstrated in the ear secretions The organisms usually disappeared in one day in the children treated with penicillin but persisted for an average of 20 days in those not given this drug Discharge from the ear continued for 6 5 days in the treated and for 36 5 days in the untreated group Ear operations were required in 3 5 per cent of the treated and in 30 3 per cent of the untreated patients Follow-up revealed that a relapse of the lesion appeared within three months in about one fourth of all the patients The frequency of relapse was considerably higher for patients under three years than for those over three The hearing acuity appears to have remained normal in those patients who had no relapse Interrupted penicillin therapy has given excellent results in suppurative otitis in children

Human Hyperimmune Serum and Streptomycin in Whooping Cough —Hatz and Burckhardt report observations on 50 children with whooping cough, aged up to two years Streptomycin was given to 25 of these Streptomycin and human hyperimmune serum was given to the other 25 patients The serum was obtained from healthy adults who had been immunized with a concentrated pertussis vaccine and who had whooping cough The gamma globulins of 20 cc of the serum of these persons are contained in 2 5 cc of the serum The results obtained were compared with a group of 50 of the same age (up to two years), who during the years 1946 1947 were treated chiefly with ascorbic acid The number and severity of attacks were greatly reduced, and the general health and appetite quickly improved in the group treated with streptomycin alone and these results were accentuated in the group treated with streptomycin and human hyperimmune serum When complications did arise, they tended to disappear more quickly in the streptomycin treated group The only side effects observed were rashes in six cases These were either rubeoliform or scarlatiniform Treatment with hyperimmune serum and streptomycin combined is to be recommended in young infants and for grave complications of older children

Amyotrophic Lateral Sclerosis After Polyarthritis W Kohler —p 1070
*Etiology of Puerperal Mastitis Experimental Studies H Muth —p 1072
Postoperative Cutaneous Emphysema After Laparotomy R Mey —p 1074

Action of Caffeine in Hypertension —According to Sebok, it is the accepted opinion that caffeine causes a general vasoconstriction and an increase in blood pressure In the brain heart and kidney, it produces vasodilatation The author attempted to ascertain whether the hypertensive effect of caffeine was a degree sufficiently great to cause caffeine to be withheld from patients with hypertension Administration of 0 05 or 0 1 Gm of caffeine to 31 patients with hypertension had the effect of lowering the systolic and the diastolic blood pressures The fall amounted to from 10 to 80 mm of mercury in the systolic pressure Maximal decrease in pressure was usually observed from 40 to 50 minutes after the administration of caffeine In about three fourths of the patients the pressure had not returned to the initial values two hours later Administration of caffeine in controls with normal blood pressure produced either a slight elevation in pressure or a reduction, as in the hypertensive patient These investigations and the fact that caffeine dilates the coronary vessels and thus improves the metabolism of the myocardium suggest that there is no justification for interdicting either caffeine or coffee in patients with hypertension

Etiology of Puerperal Mastitis —Muth states that his investigations and those of others indicate that the Staphylococcus aureus hemolyticus is the most frequent cause of puerperal mastitis Bacterium coli and hemolytic streptococci rarely cause mastitis The Staph aureus hemolyticus is frequently found in the nasopharynx of infants Some investigators assume that this organism is transferred to the maternal breast from the mouth of the infant and serves as the causal factor in mastitis Bacteriologic studies were made at the author's clinic on 200 puerperal women and their infants Smears were obtained from the nose and pharynx of 100 women during delivery and 48 hours later and from their infants 48 hours after delivery In another group of 100 women the bacterial flora of the maternal nasopharynx, the nipple and the vagina was studied during delivery and seven days later and was compared with that of the nasopharyngeal flora of the infants seven days after birth Seven days after delivery Staph aureus hemolyticus was found on 87 per cent of the maternal nipples and at the same time in the nasopharynx of 99 per cent of their infants Further observations suggested that the staphylococci were transferred from the nasopharynx of the infants to the nipple The infants seem to receive this organism from the nasopharynx of the mothers or the nurses or from the vagina of the mother Measures designed to interrupt this cycle promise to be of prophylactic value The author cites one investigator who reduced the incidence of mastitis to 0 1 per cent by applying a sulfathiazole powder to the nipples of nursing mothers

Etiology and Therapy of Seborrheal Dermatitis H Lemke —p 350

Toxoplasmosis in Infants —Walenz and Westphal observed during the past year eight infants with suspected toxoplasmosis The diagnosis could not be corroborated in four Of the four patients with proved diagnosis of toxoplasmosis, three had hydrocephalus, alterations in the cerebrospinal fluid neurological symptoms and lesions in the eyegrounds These symptoms were described in the literature as indicative of congenital toxoplasmosis In the fourth patient, only cerebrospinal fluid changes and chorioretinitis suggested toxoplasmosis The intracerebral calcifications mentioned in the literature as being characteristic of congenital toxoplasmosis could not be ascertained by roentgenoscopy in these patients Serologic verification of toxoplasmosis was possible in all four by means of the Sabin-Feldman serum dye test Examination of blood specimens gave positive titers in all the infants and their mothers This fact suggests intrauterine transmission The parasites of toxoplasmosis in two of the infants could be demonstrated either directly from the sediment of the cerebrospinal fluid or after concentration in several animal passages Although toxoplasmosis may attack any organ, in infants the parasite seems to have greatest affinity for the central nervous system Various therapeutic methods have proved largely ineffective Intrauterine death results in many cases in which toxoplasmosis is transmitted from the mother to the fetus If the pregnancy is carried to term, hydrocephalus and other serious lesions often cause death during early infancy

BOOK NOTICES

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Multiple Sclerosis and the Demyelinating Diseases. Proceedings of the Association, December 10 and 11, 1948, New York. Research Publications, Association for Research in Nervous and Mental Diseases, Volume XXVIII. Editorial Board: Henry W. Woltman, M.D., H. Houston Merritt, M.D., S. Bernard Wortis, M.D., Clarence C. Hare, M.D. Cloth. $12 Pp. 675, with 153 illustrations. The Williams & Wilkins Company, Mount Royal & Guilford Aves., Baltimore 2, 1950.

This is the second volume on multiple sclerosis which has been issued by the Association for Research in Nervous and Mental Diseases, the first having appeared in 1921. This volume consists of 40 papers contributed by 68 authors, covering the general subjects of history, ecology, etiology, blood flow, anatomy and chemistry, pathology, clinical aspects and treatment and rehabilitation in multiple sclerosis. The foreword, by H. Houston Merritt, S. Bernard Wortis and Henry W. Woltman, is an admirable summary of the present status of the multiple sclerosis problem, although it presents as established fact some of the wholly tentative statistics on incidence and prevalence, based on a single study made in Rochester, Minn.

Walter Timme, in the first paper in this volume, discusses the history of multiple sclerosis and summarizes the findings and conclusions of the 1921 meeting of the association. This paper serves as an excellent introduction and background to the remainder of the volume. In the section on ecology of multiple sclerosis (which would ordinarily be called epidemiology), Charles C. Limburg presents an analysis of mortality statistics; Alexander R. MacLean, Joseph Berkson, Henry W. Woltman and Louise Schionneman report on a study of the population of Rochester, Minn., and Lawrence C. Kolb reports on studies made in the Eastern Health District in Baltimore. In general, Limburg agrees with the hypothesis that mortality from multiple sclerosis is positively associated with a cold climate, although the evidence he presents is not entirely convincing. These three papers present varying estimates of the prevalence of multiple sclerosis of 35, 55 and 15 cases per 100,000 population. Kolb states that in the Eastern Health District there were twice as many patients, over a 10 year period, seeking aid for multiple sclerosis as for residual paralysis following acute poliomyelitis. He notes that there were little or no attempts at rehabilitation, many patients occupying hospital beds for long periods, and that the medical services provided for these patients were chiefly diagnostic. The discussion of these papers brought out the observation that there was apparently considerable difference in disability and mortality between private patients and clinic and ward patients.

Hans H. Reese discusses the theories concerning the etiology of multiple sclerosis, points out the probability that the etiological factors are multiple and discusses the various theories under the headings of infection, venular thrombosis, vascular spasm, allergy and nutrition. Roland P. Mackay, in a discussion of the familial incidence, concludes that there is a familial factor which is insufficient by itself to produce the disease. Tracy Putnam's review of the pathogenesis of multiple sclerosis, if accepted, points to injuries, infections, a cold, damp climate and pregnancy as factors precipitating acute exacerbations. In treatment, Putnam recommends the use of bishydroxycoumarin (dicumarol®) and diphenylhydantoin (dilantin®) sodium as promising agents in prevention of acute episodes. (A more recent critical review of the subject by George A. Schumacher [The Journal, Aug. 5, 1950, p. 1241] rejects the evidence for these conclusions as inadequate.) The clinical features of multiple sclerosis are well analyzed in a report by Sidney Carter, Daniel Sciarra and H. Houston Merritt of 56 cases proven by autopsy.

An interesting discussion of the role of psychodynamic factors in the etiology of multiple sclerosis is comprised in three papers on the subject by Roy R. Grinker, George C. Ham, Fred P. Robbins; by R. Harrower, and by Francis J. Braceland and Mary E. Giffin. Grinker and his associates describe what they consider a characteristic premorbid state of multiple sclerosis as that of "great immaturity since early infancy," a strict mother, a nondominant father, absence of warm relations with other people, no free anxiety and a precipitating factor for overt symptoms of some major change in the life situation. Braceland and Giffin, on the other hand, conclude that there are no specific characterologic personality changes in multiple sclerosis Harrower, on the basis of a battery of psychological tests, concludes that patients with multiple sclerosis show less anxiety over their disability, more acceptance of dependency, less awareness of conflict and an excessive cordiality, as compared with control groups. Otto R. Langworthy, in his paper on maladjustment problems in multiple sclerosis, concludes that "we have no clear evidence at present that emotional factors can contribute to the development of the lesions of multiple sclerosis through change in blood vessels or otherwise."

This is a volume well worth reading for anyone interested in the problem of multiple sclerosis. It is to be hoped that a summary of the apparently established facts, especially with regard to diagnosis and prognosis, will be made available to the general practitioner, who very much needs to know of the importance and of the relatively more hopeful aspects of this widespread disease.

Chirurgie der Urogenitalorgane: Indikation und Technik. Von Prof Dr. H. Boeminghaus. Band I: Nieren, Harnleiter. Band II: Blase, Prostate, Samenblasen, Hoden, Nebenhoden, Samenstrang und Skrotum Band III: Penis, Harnrohre, Anhang, Neuro-chirurgische Eingriffe bei Erkrankungen der Urogenitalorgane. Cloth. Pp. 251; 243; 228, with 519 illustrations. Werk-Verlag Dr. Edmund Banaschewski, (13b) Bad Worishofen, 1950

Book 1 describes surgery of the kidneys and ureters; book 2, surgical treatment of the urinary bladder, prostate, seminal vesicles, testes, epididymis, spermatic cord and scrotum; book 3, surgical procedures employed for pathologic conditions of the penis and urethra. An appendix on neurosurgical procedures in therapy of the urogenital apparatus is included.

It is obviously impossible to enter into a detailed analysis of all the procedures described. However, the over-all impression, after thorough reading, is favorable, for the work is of a practical nature, dealing particularly with the indications for operation in cases of diseases of the genitourinary apparatus and the surgical technic best adapted thereto. It is obvious, as the author points out, that didactic text and artistic illustrations, no matter how excellent in themselves, are never sufficient to create a surgeon; practical experience must supplement theoretical knowledge. Evaluated on these premises, the work serves an excellent purpose. The text is thorough, and the illustrations profuse. Most of the latter are diagrammatic, but all are adequate and clear.

It seems that, since the war years restricted scientific intercourse in European countries, there is a keen desire among surgeons there to keep abreast of modern surgical procedure The fact is well evidenced in this work, for the procedures are admirably presented, without padding. The literature is abstracted exceptionally well; in the section on surgery of the prostate, Millin's procedure is particularly well described and illustrated. In his discussion of urinary incontinence, the author does not limit himself to consideration of surgical procedures adapted to the male patient but includes those employed for the female patient as well. In the appendix, one finds ably presented sections dealing with elimination of pain in operations on the kidney, bladder, prostate, rectum and external genitalia, with the approach in treating oliguria, anuria and uremia and with various procedures used in the treatment of impotentia generandi. A conservative analysis of the so-called reactivation procedures for senility is also given. The experimental work of Harms, Steinach, Sand and others is thoroughly analyzed, with the conclusion that transplantation of testicular material will give results only when there is definite evidence of organic failure of internal secretion of the testes. A conservative attitude is taken here, as well as in analysis of the results of the Steinach procedure. Postoperative complications are well presented, as are the neurosurgical procedures related to pathological conditions of the genitourinary apparatus, as: renal denervation, the surgical treatment of hypertension as related to renal pathology, resection of the hypogastric nerves, chordotomy and alcohol injections for the relief of pain.

Those who read German will find this work a worth while addition to their libraries. This applies to the student, the general surgeon and the specialist as well.

B.C.G. Vaccination in Theory and Practice. By K. Neville Irvine, D.M., M.A., B.Ch., Medical Superintendent, Smith Isolation Hospital, New York City. With a Foreward by Konrad Birkhaug, B.A., M.Sc., M.D., Chief of the B.C.G. Laboratory, New York State Department of Health, Albany. Cloth. $3; 9s.6d. Pp. 130. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, 48 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1949.

Since the introduction of BCG vaccine and its first use in 1922 in infants, probably no preventive measure for the control of tuberculosis has aroused so much controversy. This book attempts to review the literature on BCG vaccination and to give practical details of the technic of vaccination. The evolution of the BCG strain is traced. The theory underlying BCG vaccination is stated, and the various methods of vaccination used at different centers are detailed. The stability of the virulence of BCG and the safety of the vaccine are considered. There is also an effort to investigate the degree of resistance produced by the vaccination, and consideration is given to the practical aspects of BCG vaccination. The material is clearly presented throughout the book.

There are, however, many who will disagree with the author's statement that "At long last BCG vaccination has been universally accepted as a valuable weapon for our armament in the fight against tuberculosis." The author leaves unanswered the question of the efficacy of BCG vaccine but believes that the exact degree of efficacy is important only if the BCG vaccine is to be used to replace any of the well accepted antituberculosis measures.

Tissue Culture Technique. By Gladys Cameron. Second edition. Cloth. $4.20. Pp. 191, with 51 illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1950.

Contrary to the popular belief that tissue culturing is a recent innovation in medical science, the fact is that in vitro growth of tissues was accomplished in the latter part of the last century. Improved and modified technics have subsequently been developed according to the type of cellular activity under study.

Tissue culture consists of aseptic transfer of tissues from a living organism to an in vitro environment which provides optimum conditions of nutrition, aeration and temperature for cell proliferation, organization and function. Catabolic products necessarily must be removed to prevent death of the cells, and nutrients must be supplied in excess. The author obviously is cognizant of the difficulties encountered in the practical procedures outlined and has painstakingly incorporated details of technic which both the beginner and advanced worker will appreciate. Too often technical details are not given in published procedures; this results in waste of materials, loss of time and frustration of the investigator. The author stresses the need for knowledge of cytology to insure proper interpretation of results obtained by these technics.

The volume is a practical laboratory guide for the culture of tissues. It emphasizes the fact that the technics are relatively simple and require little specialized equipment but demand technical skill and knowledge of normal cytology of the cultured material. In addition to the technical procedures, the volume contains chapters on micromanipulation of tissue cultures, histological technics and photomicrography of tissue cultures. An extensive bibliography and a list of suppliers of special equipment are appended.

The Diagnosis of Salmonella Types. By F. Kauffmann, M.D., Chief, International Salmonella Center, State Serum Institute, Copenhagen, Denmark. Publication Number 62, American Lecture Series, A Monograph in American Lectures in Tests and Techniques. Edited by Gilbert Dalldorf, M.D., Director of the Division of Laboratories and Research, New York State Department of Health, Albany, New York. Cloth. $2.25. Pp. 86. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

Diarrhea, typhoid and paratyphoid fevers, food poisoning, bacteremia, bone infections and even infections of the central nervous system are manifestations of the pathogenicity of the Salmonella group in man. The organisms are also found in rodents, horses and birds, including chickens. Differentiation of typhoid from paratyphoid fever and the incrimination of the agents responsible for gastroenteritis caused by Salmonella necessarily are dependent on isolation and identification of the organisms. Salmonella typing has considerable epidemiological value. Immunologic differentiation of these organisms has been emphasized since the 1920's; prior to that time they were separated on the basis of physiological characteristics. An absurd number of new species have been described solely on the basis of immunologic differences; it now appears more logical to subdivide the serotypes into biochemical types by biochemical methods, and this is the author's approach. This handbook incorporates details of methods for preparing antigens, vaccines and immune serums, performance of agglutination and absorption tests, tables for identification of antigens and methods for serologic diagnosis. An appended section indicates types of media, with formulas which the author considers optimum for the procedures employed. The author is an authority in this field, having been appointed chief of the International Salmonella Center at the State Serum Institute, Copenhagen, Denmark, established by the World Health Organization in 1948. Several American state health departments have been designated to collaborate with the International Center for the collection and identification of Salmonella strains.

Counseling the Handicapped in the Rehabilitation Process. By Kenneth W. Hamilton, Associate Professor of Social Administration, Ohio State University, Columbus. Cloth. $3.50. Pp. 296, with 4 illustrations. The Ronald Press Company, 15 E. 26th St., New York 10, 1950.

This is a textbook written by a well qualified teacher in the field of rehabilitation. The book is written for "all who counsel the handicapped on their problems—social workers, psychologists, physicians, therapists, and employment counselors." It is documented fully and has many interesting illustrations.

The text emphasizes the role of the rehabilitation counselor in bringing to the use of the disabled person "individualized and coordinated professional services." Emphasis is placed on considering the total needs of the disabled person—physical, mental, social, vocational and economic. The book begins with a discussion of the nature and purpose of rehabilitation, then covers the rehabilitation process and development of community resources and finally treats the problem of the evaluation of the results of rehabilitation. As may be apparent, the rehabilitation theme is developed logically and in this regard probably represents the best systematization to appear to date. There is an interesting treatment of the distinction between disability and handicap, basic in the development of a rehabilitation program. Physicians may feel that insufficient attention is given to medical-physical factors in chapter 4 where areas to be studied are discussed, but close perusal will show that there is as much coverage as is given to psychological and emotional, educational, social and vocational factors. Particularly important to physicians interested in community aspects of rehabilitation are chapters 7 through 10, dealing with such topics as community organization, the severely handicapped in the local community and the rehabilitation center. The central theme of the book is contained in chapter 8, on the rehabilitation counselor. Here, stress is placed on the need for special training programs for this new specialty for which current programs in social casework and vocational counseling are inadequate in the opinion of Professor Hamilton.

Some may disagree with the emphasis given to the selection of suitable employment as the "crowning achievement of the rehabilitation process" and feel that sufficient recognition of self-care as a goal is not appreciated fully. However, Professor Hamilton is concerning himself with the majority of disabled persons and demonstrates adequately his understanding of setting other goals for the severely disabled. This book should be found in the libraries of any physician interested in the process of rehabilitation at the community level. Its systematic approach to the problem is to be recommended highly.

The Cerebral Cortex of Man: A Clinical Study of Localization of Function. By Wilder Penfield, C.M.G., M.D., B.Sc., Professor of Neurology and Neurosurgery, McGill University, Montreal, and Theodore Rasmussen, M.D., Professor of Neurological Surgery, The University of Chicago, Chicago. Cloth. $6.50. Pp. 248, with 121 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1950.

This book is based on the Lane Medical Lectures which Penfield gave in 1947. Four hundred craniotomies performed between 1928 and 1947 presented the opportunity to stimulate various parts of the cerebral cortex with electrical currents and to record the objective (movements) and subjective effects. The results of these studies are presented clearly and with the necessary details. Objective results and interpretation are sharply separated. The investigations give a very complete description of the organization of the sensorimotor cortex. The primitive character of the movements is emphasized. They are "not more complicated than those the newborn infant is able to perform." Evidence of the existence of a secondary motor cortex is also presented. A certain muscle may show widely separated cortical foci when it is used in different functional groupings. Central overlap exists clearly in precentral and postcentral gyrus. The authors assume that the diencephalon plays an important role in the elaboration of movements. A considerable part of the book is devoted to observations on the effect of stimulation of nonmotor areas. Perhaps the most interesting phenomenon which Penfield and Rasmussen discovered is the fact that electrical stimulation of the temporal lobe elicits illusions, hallucinations and dreamlike conditions which suggest that the temporal lobe plays an important role in memory. Whereas stimulation of the sensorimotor parts of the brain results only in primitive movements or sensations, that of the temporal lobe activates "acquired synaptic patterns." The book is one of the most important contributions to neurosurgery and physiology which has appeared in many years. It is beautifully printed and illustrated.

Human Milk: Wartime Studies of Certain Vitamins and Other Constituents. By S. K. Kon and E. H. Mawson. Medical Research Council Special Report Series No. 269. Paper. 4s. Pp. 188, with 19 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W.C.2, 1950.

This study is an important contribution. It advances greatly our knowledge of the composition of individual samples as influenced by such factors as the mother's state of nutrition, the stage of lactation, the milk yield, the season of the year, the age and parity of the mother. The report is well planned for ready reference. It is divided into two chief sections. One deals with the constituents of human milk and the other with the relation between the constituents studied and nutritional standards. Tables and figures are used to good advantage. The language is clear and concise and easily read. Each subsection is followed by a bibliography of related studies. The report is summarized in a few short pages at the end of the book.

It is impossible to illustrate the many points of special interest to pediatricians, obstetricians and public health workers which are brought out in this book. However, the book is inexpensive and can be easily obtained by all professional persons who are concerned in any way with the problem of lactation. Nevertheless, for purposes of illustration, attention is called to the fact that it may be misleading to apply to human milk conclusions drawn from the study of cow's milk. For example, the vitamin A content of human milk, which is initially high, falls rapidly the first three weeks and then falls gradually, until it reaches one third of the original value. On the other hand, thiamine increases rapidly until it levels off at the fifth week. This is the reverse of what happens with the cow. Seasonal variations are likely to be noted in the vitamin A content of cow's milk, whereas this does not seem to be true of human's milk. This study is an impressive achievement.

Saints, Sinners and Psychiatry. By Camilla M. Anderson, M.D. Assistant Clinical Professor of Psychiatry, University of Utah, Salt Lake City. Cloth. $2.95. Pp. 206. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St. London, W.C.2; 2083 Guy St., Montreal, 1950.

This book appears to confirm the idea that under the critical eye of the psychiatrist "normal" as applied to behavior of the struggling human race is an adjective tolerated only in honor of tradition. Unlike so many authors in this field, Anderson does not hem and haw in polysyllabic jargon. She says directly what she wants to say, in language easy to understand. Case histories are presented without customary drawn-out discussion; they portray the essentials in one or two paragraphs, without the irrelevant fantasy and romance so frequently encountered in psychiatric reports.

The book presents a novel and sensible interpretation of the dynamics of human behavior. It postulates that behavior is a culmination of psychological structure and function. Structure involves the individual as a personal entity with all the psychological components of a human being striving toward recognition. Function is an expression of these components, and the cumulative result sets the pattern of behavior. Illustrations of this mechanism follow:

Structure	Function
I am the baby	I get special consideration
I am the oldest	I get the hardest jobs
I am smart	I get approval
I am dumb	I get picked on
I am a nuisance	I get attention
I am honest	I get approval
I don't trust people	I don't get disappointed
I am a sissy	I get Mamma's love
I am selfish	I get something
I am different	I don't have to compete
I am fatherless	I mean more to women
I am awkward	I am relieved of many jobs
I am mistreated by father	I get more from mother

Throughout childhood, behavior is modeled in accordance with the approval-disapproval reactions shown by the persons significant to the growing organism. Parents, siblings, grandparents, aunts, uncles, teachers and playmates all exert their influence on the ultimate character of the person. And being, as everyone was and indeed remains, at the mercy of so motley a combination of personalities, is it any wonder that everybody is neurotic? Saints or sinners, we are all the product of our early environment—a concept not too different from the Watsonian prince-pauper conditioned-reflex theory of a quarter of a century ago.

The book was apparently meant for popular use. The physician, however, will find it interesting. It is full of wholesome material for daily application in sociomedical study and psychosomatic medicine, and can be recommended for its instructive features and practical philosophy as much as for its delightful style and easy readability.

Studies in Population: Proceedings of the Annual Meeting of the Population Association of America at Princeton, New Jersey, May 1949. Edited by George F. Mair. Paper. $2.50. Pp. 169. Princeton University Press, Princeton, New Jersey, 1949.

This book will be of interest and value to those persons interested in our current and future population problems and trends. The five sections of the book represent the five sessions of the meeting: two on current problems and technics, one on food resources and two on fertility. The first section, Application of Demographic Data to Current Problems, contains papers on the relative importance of mortality and divorce in the United States, on the length of the working life and on a series of illegal abortions. One speaker pointed out that, in view of the rapid rise of the divorce rate during recent years, it is significant that the trend in total marital dissolutions has shown a less alarming picture; the rise in divorces is being offset by the continued decline in marriages dissolved by death. Typhoid fever, tuberculosis and the hazards of childbirth, "the great homebreakers of the past," have been virtually eliminated by recent advances in medical science, sanitation and public health. Another speaker pointed out that, on the basis of census data, the average male worker of 20 years of age in 1940 had a life expectancy of 46.8 years and a labor force life expectancy of 41.4 years.

Included in the second section, Tools for Demographic Research, is a brief explanation of the sampling method used in the current population surveys of the Bureau of the Census. In this monthly "miniature census," about 25,000 households in 68 counties are interviewed for information on a variety of subjects. The papers also concerned the various recent proposals for modifying the net reproduction rate and the use of census tracts and divisions in the recording of the 1950 census data in the state of Washington. Soil resources and potential food supply and their effects on population increases are discussed in the papers in the section on Resources for the World's People. One speaker assures us that "we need have no fear in this country of declining levels of food consumption because of past abuse of our lands—not even, as will appear presently, after allowing for all the exports other nations will buy from us" (page 54). Another warns that ". . . even if we could increase food production for the next few decades twice as fast as appears probable we cannot be at all certain that when the end of such a period arrived most men would be any better off than they now are, unless, in the meantime, we had learned how to control our own conduct as regards the rate of reproduction" (page 92).

In the section Value Systems and Human Fertility are included analyses of the reproductive mores of the Asian peasants and of the people of the Middle Ages which attempt to show that fertility rates cannot be studied apart from the total cultures. In one paper it is pointed out how the Catholic value system influences the fertility aspects of behavior.

In discussions on the Future Course of Research in Fertility, a physician presents current medical thinking on the "physiologic aspects of the control of fertility" and the more important advances in this area. Other speakers pointed out the measures and methods to be used in future studies of fertility as well as some of the fields in which study is needed.

The American Family: A Factual Background. Report of Inter-Agency Committee on Background Materials. National Conference on Family Life, May 1948. Paper. Pp. 457. U. S. Government Printing Office, Washington, D. C., 1949.

The general purpose of the Conference on Family Life was to discover specific means by which the American family might be strengthened for the benefit of its individual members and society. This volume contains material on the basic family and population statistics; the family in the American economy, education, health, housing, legal status, income maintenance and social services to families.

The term "family," as revised by the Bureau of Census, is "A group of two or more persons living together and related by blood, marriage, or adoption; all persons residing together and related to each other are regarded as one family." Population and family trends, marriage and divorce rates, mortality statistics and migration statistics are among the many items covered in the first chapter. Chapter 2, The Family in the American Economy, discusses trends in the labor force participation, the number of workers per family and the number of women workers in the family. Recent changes in family income are treated in this volume, and the trends of consumer expenditures for various products are presented in the form of tables. Statistics on the relation between education and marriage were developed, such as education as it relates to family living. Trends in school attendance of children and shifts in distribution are treated at great length, with the inclusion of many tables presenting data by age and by states. Family health has been related to such factors as prenatal influences, infancy and childbirth, environmental sanitation, housing conditions, income and the receipt and costs of medical care. There are tables of the percentages of births in hospitals in each state, infant mortality by state and the number of children crippled by various diseases. The conditions and facilities of the housing of families are discussed in chapter 5, Housing for American Families. Also included in this chapter is information on the amount of overcrowding, size of households, impact of wars and trends toward rural, nonfarm areas. Estimates of needs of future housing have also been made. Chapter 6, Legal Status of the Family, discusses the property rights and powers of contract of husband and wife, the custody, control and earnings of minors, laws affecting the school attendance, annulments and divorce. Income maintenance programs regarding social insurance and public assistance are presented in chapter 7. Also discussed in this chapter are the family and child welfare services, as well as various other social services to families. Many tables are presented of mortality and natality statistics, family income and distribution of personal income, consumer expenditures, school enrolments, number of teachers in schools, dwelling units and various insurance plans. Most of the statistics are for the years 1945, 1946 and 1947, with some historical trend tables. This volume contains a wealth of knowledge about the various factors relating to the American family.

Elements of Medical Mycology. By Jacob Hyams Swartz, M.D., Assistant Professor of Dermatology, Harvard Medical School and Postgraduate School, Boston. In Collaboration with Ethel M. Rockwood, M.D., Dermatologist, Massachusetts General Hospital, Boston. Introduction by Fred D. Weidman, M.D., Professor of Dermatological Research, University of Pennsylvania, Philadelphia. Second edition. Cloth. $5.50. Pp. 240, with 138 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1949.

Problems of the pathognomy, diagnosis and therapy of fungus diseases are encountered daily by physicians; their resolution remains one of the engimas of modern medicine. Relatively few American textbooks have been published on the subject during the past two decades, and none adequately covers the field of mycology. With the advent of chemotherapeutic agents, including the antibiotics, increased interest in medical mycology has been manifested by physicians in the hope that cures of fungus diseases could be effected by those agents. With the exception of the sulfonamides and penicillin for the treatment of actinomycosis, none of those agents has proved to be effective against surface or systemic fungus infections. Therapy of the majority of these diseases has changed little throughout the years; cures of the systemic infections are comparatively rare.

This volume represents a handbook of medical mycology and will prove a valuable addition to the reference volumes on every physician's bookshelf and in clinical laboratory libraries. It is not a complete reference book but contains practical information on the pathogonomy, diagnosis and therapy of many pathogenic fungi. In many respects it supersedes the "Manual of Clinical Mycology," published in 1945 under the auspices of the National Research Council. The author, a disciple of Carroll W. Dodge, has followed the latter's classification of the fungi and has arranged the subject matter, including an excellent chart of the pathogenic fungi, according to fungus genera. The chapter on the diagnosis of fungus infections by specific procedures reflects the interest and practical experience of the author in the laboratory aspects of the subject.

Epidemiology in Country Practice. By William Norman Pickles, M.D., Medical Officer of Health, Aysgarth Rural District, Yorkshire. With a Preface by Major Greenwood, F.R.S., D.Sc., F.R.C.P., Professor of Epidemiology and Vital Statistics in the University of London. Re-issued 1949. Cloth. $2.50. Pp. 112, with illustrations. The Williams & Wilkins Company, Mount Royal & Guilford Aves., Baltimore 2, 1939.

This book was first published in May 1939, after which the demand for it was regular and continuous until April 1941, when the entire bound and sheet stock and the type were destroyed by enemy action. In response to numerous requests, the publishers had it entirely reset and republished in virtually the same form as when first issued. The reader who expects to find epidemiological data on large numbers of cases will be disappointed. It might well be called an essay on epidemiology in country practice. It includes several papers published by the author from time to time in medical journals. It is intended for the general practitioner and illustrates well that there is a vast amount of epidemiological information to be gleaned from clinical observation in one's own practice.

Major Greenwood says in the preface, "Budd was one of the last of those physicians who did their own epidemiology, and were not content to sow for others to reap. We have, indeed, had to wait a long time for a second Budd but (in Dr. Pickles) I think we have found one." The author has written as the local health officer and general practitioner in an isolated rural community. His close association with the people and his intimate knowledge of them gave him the unique opportunity to make and record firsthand observations on the entire course of diseases as related both to the individual and to the community. This is particularly true with regard to unusual opportunities to determine definitely the incubation period in many patients. The lack of large numbers of observations is offset by the completeness and thoroughness of those made by the author in establishing his own epidemiology.

A practical common sense point of view is obvious. The opinions expressed as to management of communicable diseases, the relative value of hospitalization, quarantine, isolation and other procedures are as sound now as they were when they were written. The commoner communicable diseases are described as they occur in the author's practice. There are interesting chapters on epidemic catarrhal jaundice and epidemic pleurodynia (myalgia). In addition to the technical information the book contains, it has much of historical interest; and the wit, philosophy and common sense woven in make it pleasant and interesting reading. If it creates a desire in the general practitioner to study the course of communicable diseases in the patient and the community, as the author did, it will have served a good purpose. The paper and printing are good; there is a bibliography and a complete index.

Aus den Anfängen der Psychoanalyse: Briefe an Wilhelm Fliess, Abhandlungen und Notizen aus den Jahren 1887-1902. Von Sigm. Freud. Cloth. 30s. Pp. 477, with illustrations. Imago Publishing Co., Ltd., 10 Nottingham Place, London W.1, 1950.

This book contains selections from a correspondence between Sigmund Freud and the Berlin physician and biologist Wilhelm Fliess and some notes and manuscripts on the etiology of the neuroses, anxiety, melancholia and hysteria. The letters presented here are those which Freud addressed to Fliess. They were discovered in an antique book market together with other effects of Fliess. The letters which Fliess sent to Freud have not been found. Freud was between 31 and 46 years of age when these letters and manuscripts were written. This was the time when he first established himself as a specialist for nervous diseases. He discussed with his friend Fliess his plans, successes and failures. The letters contain not only those ideas which finally were elaborated into Freud's psychoanalytic theories but also the bypaths and false starts, thoughts and conclusions which he later rejected. Marie Bonaparte, Anna Freud and Ernst Kris arranged this material for publication. They selected 168 communications of a total of 284, giving emphasis to those which were concerned with the scientific investigations of the writer and those which throw light on the social and political conditions of the time. They are aware of the fact that Freud would not have published any of this material, for he never presented to the public anything that was not complete. They feel, however, that this material, which was saved from destruction by a lucky accident, throws new light on the development of the theory of psychoanalysis and that it will be of interest to those who are familiar with Freud's published works.

The Nutritional Improvement of Life. By Henry C. Sherman. Cloth. $3.75. Pp. 270. *Columbia University Press, 2960 Broadway, New York 27, 1950.*

Dr. Sherman has drawn on his lifetime of writing and research in the field of nutrition to present a comprehensive review of the advances made in the science of nutrition up to the middle of the twentieth century. The language used is simple and nontechnical. The significance of the discoveries of nutritional research is presented rather than the technics employed. As Dr. Sherman remarks in the preface, "Nutrition is everyone's adventure. This book brings out the human implications. It differs from others in its field—and from scientific books generally—in that it deals less with how the advances of yesterday were made, and more with what they can mean for today and tomorrow."

The first part of the book follows the progress of nutrition throughout the half century of its recognition as a distinct science. The latter part of the book contains an excellent discussion of current nutritional developments and their implications for the betterment of life. An appendix contains a summary of the 1946 World Food Survey of the United Nations' Food and Agriculture Organization. A second appendix gives records of actual meals which illustrate how the present day knowledge of nutrition can be applied to an average twentieth century diet. A carefully selected bibliography which includes abstract as well as original references concludes the book. Anyone who has an interest in the science of nutrition will find this book of value. Its nontechnical language will appeal particularly to laymen and students. It is an excellent book for the physician to recommend to those of his patients who desire an easily read reference on nutrition and its effect on human life.

The Physiology and Pathology of Exposure to Stress: A Treatise Based on the Concepts of the General-Adaptation-Syndrome and the Diseases of Adaptation. By Hans Selye, M.D., Ph.D., D.Sc., Professor and Director of the Institut de médecine et de chirurgie expérimentales, Université de Montréal. Preliminary edition. Paper. $14. Pp. 792, with illustrations; 203R. Acta Endocrinologica, Inc., 5465 Decarie Blvd., *Montreal 29, 1950.*

The author has played a primary role in the development of the theory with which this impressive volume deals. In this carefully developed treatise, the principal facts and theories on which the general adaptation syndrome concept is based are thoroughly discussed. Definitions of terminology used are outlined, and the various alarming stimuli or factors which elicit the syndrome are described. Whether one agrees with the concept of the syndrome or not, work with pituitary adrenocorticotropic hormone (ACTH) and cortisone has lent support to many of the basic concepts on which its theory depends.

If future events prove that this concept is correct, it will prove to be one of the significant medical advances in understanding the nature of disease of this century. One can carp at the somewhat rigid division of the adrenal steroids into mineralocorticoids, glucocorticoids, medulloids, lipocorticoids and others, since many of the steroids have been shown to have significant actions in several of these fields. However, the general stature of Selye's work requires no defense. Every serious student of internal medicine and endocrinology is almost constrained to familiarize himself with this textbook. The bibliography is most thorough.

The Physiology of Work and Play: A Textbook in Muscular Activity. By Sarah R. Riedman. Cloth. $4.90. Pp. 584, with 158 illustrations by Ida Scheib. The Dryden Press, Inc., 386 Fourth Ave., New York 16, 1950.

As stated in the preface, this volume is primarily a textbook on the physiology of muscular activity written for undergraduates in physical education, physical therapy and recreation. The well-organized table of contents indicates that the book is divided into five parts. Part 1 considers muscle physiology, fatigue and the nervous control of muscular activity. Part 2 discusses cardiovascular-respiratory functions in relation to exercise. Part 3 is concerned with the internal environment of the body and changes occurring in the blood, tissue fluid and lymph as a result of skeletal muscle activity. Part 4 discusses skeletal muscle activity and work under such limiting environmental conditions as unusual barometric pressures and extremes of temperature and humidity, as well as under conditions of modern industry. Part 5 contains information of interest to the practicing physician with reference to convalescence and reconditioning, therapeutic exercises, physical fitness, somatotypes and psychosomatic interrelations of the nervous and skeletal muscle systems.

Since the scientific background of physical education students is not uniform, the author includes pertinent material on gross anatomy, histology and chemistry. The basic and applied physiology of exercise are well presented, but in some instances accuracy has been sacrificed for brevity and simplicity. Thus it would be more accurate to say that for all practical purposes cardiac muscle cannot be tetanized rather than that "cardiac muscle can not be tetanized at all" (page 32); and that immobilization of a limb decreases rather than "prevents the flow of impulses both to and from a muscle" (page 52). The cerebellum aids importantly in postural reflex mechanisms but is not a center for postural reflexes (page 195). Contrary to the information on page 212, atropine decreases sweat secretion. The cardiac output values quoted on page 270 and obtained by the acetylene method have in recent years been shown by the cardiac catheterization technic to be too low. Contrary to the statement on page 371, the capillary wall is only relatively impermeable to the plasma proteins. There are also a few confusing typographic errors, such as "the R.Q. was 9 and 9.5" (page 85), and "running increased the f.f.f. [flicker fusion frequency] by 80 to 90 per cent" (page 156).

The style is clear, the illustrations are satisfactory, and the index is adequate. A good summary and pertinent reference list are included at the end of each chapter. The format of the book is in keeping with its list price. This volume is recommended for students of physical education, physical therapy and recreation, as well as others interested in this field of human physiology. Physicians will find part 5 of value.

Professional Nursing: Trends and Adjustments. By Eugenia Kennedy Spalding, R.N., M.A., Professor of Nursing Education, Indiana University, Bloomington, Ind. Fourth edition. Cloth. $4. Pp. 730, with 29 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House, 10-13 Bedford St., London W.C.2; 2083 Guy St., Montreal, 1950.

This book has been extensively revised and enlarged to give a fuller understanding of the many social, economic, professional and other factors that are directly related to the nursing field. First, there is an introductory section describing the technic of collecting, evaluating and organizing source material essential in the study of nursing problems and methods of professional readjustment. In unit 1, the Social and Professional Outlook of the Graduate Nurse, the discussion centers on nursing as a profession, recent advances and current problems that may affect the future of nursing. The succeeding section contains a survey of occupational opportunities for professional nurses, information on nurses in public service, selection of work, continuation of education and the procedure for obtaining employment and resigning from a position. Unit 3 presents up-to-date information on the activities of professional organizations in the nursing field and also discusses nursing and related legislation, public relations in nursing and the organizational principles and practices which aid in professional activities. The concluding section concerns legal relations, problems of economic security and professional relations with physicians, patients and their families and other members of the nursing staff. Suggestions are also made with reference to mode of living, leisure activities, personal appearance, gracious manners and tact.

This book is written primarily for the professional nurse and offers a wealth of information on nursing organization activities and relations that will be helpful in making readjustments to individual problems. Methods of procedure are fully described in each chapter, and there are an extensive bibliography and suggested references.

The Theory of Camping: An Introduction to Camping in Education. By Frank L. Irwin, Ed.D. Cloth. $2.50. Pp. 173. A. S. Barnes and Company, 101 Fifth Ave., New York 3, 1950.

Different from many books on the subject, this volume is concerned chiefly with the educational aspects of camping and with ways of integrating the objectives of camping with the general purposes of education in America. While the methods through which camping can help to achieve educational goals are outlined, as the title indicates, the book is in no sense merely a manual of camping activities. Instead, it seeks to present the basic principles of good camping on which specific programs may be built in particular situations. Organized camping is defined as an educational enterprise providing children with an opportunity to live, work and play in a group situation to obtain experience and insight into many of the basic processes of life and to receive guidance from a mature counselor who influences the camper all during the day over an extended period of time. After tracing the development of camping in the United States, the author shows how a properly organized and conducted program can contribute to self reliance, economic efficiency and civic responsibility and at the same time provide unusual opportunity for experience and training in human relations. The importance of understanding the individual camper and meeting his personal needs within a situation that inherently stresses group living is emphasized. The camp program is then considered with stress on the vital role that good counseling and administration play in providing a worth while schedule of activities. A description of day camps and public school camping, together with up-to-date bibliographies, add to the usefulness of the volume. Physicians concerned in any way with camping will be particularly interested in the section on health and safety which, although brief, provides satisfactory coverage of the health service aspects of camping.

The American Red Cross: A History. By Foster Rhea Dulles. Cloth. $5. Pp. 554. Harper & Brothers, 49 E. 33rd St., New York 16, 1950.

Written with an approach that shows no bias, this historical review presents the story of the American Red Cross ably and completely. It is essentially a condensation and extraction of a series of monographs prepared by a special division set up within the organization. The author also had access to official records and states specifically in his preface that no restrictions or pressures were applied to influence the way in which those were used.

Personalities are always interesting subject matter, and the author shows special skill in the presentations scattered throughout the book of important personages who have guided the Red Cross over its lifetime of more than 70 years. Perhaps the most unusual of these was the founder, Clara Barton. Although growth of the Red Cross might now seem to have been the most natural and inevitable thing in the world, actually it was a struggle that called for perseverance and faith on the part of those associated with its early beginnings and the "growing pains" from which it suffered at intervals. These are described with candor in three different chapters, one on controversy and reorganization, another on criticism and reform and the third on the Red Cross and the New Deal.

In addition to the 30 chapters describing the Red Cross, its services in war and in peace, international operations, volunteer activities, special features, such as the blood donor program and aid to prisoners of war, a final chapter lists in specific detail the source material on which the author was able to draw. As the author states, this is the first complete history of the Red Cross. It is a thoroughgoing piece of work that should be of widespread interest for persons in all levels of society.

Developments in Diphtheria Prophylaxis. By Lewis B. Holt, M.Sc. Cloth. 12s. Pp. 181, with illustrations. William Heinemann Medical Books Ltd., 99 Great Russell St., London W.C.1, 1950.

In 1926, Glenny and others demonstrated that the antigenic power of alum precipitated diphtheria toxoid was greater than that of the plain or nonprecipitated product. The newer preparation proved too irritating for administration to children, but it was later found that careful washing of the precipitate provided a product which could be used for human immunization.

Alum precipitated diphtheria toxoids often vary in potency even under regulated and well controlled methods of production. These variations, with their attendant problems of adequate diphtheria prophylaxis, prompted the author's search for a reliable and accurately reproducible prophylactic of high potency and stability. The work includes the description of a method for preparation of such a product and of the antigen and the alum precipitate.

Data are presented which reflect the effect of *p*H, temperature, formalin concentration, minerals, types of aluminum salt and other variables on the quality of the toxoid prepared.

Considerable space is devoted to a critical review of the current theory, postulated by Glenny, that the increased antigenic efficiency of alum toxoid is due to slow absorption and elimination. An alternative explanation, supported by experimental data, is offered for the greater physiological activity of the precipitated toxoids as compared with their parent formol toxoids. It is postulated that the optimum amount of alum is of far greater importance than the amount of antigen, since when the amount of mineral carrier (alum) is increased, the antigen is efficiently distributed among a large number of antibody-producing cells. The author suggests the possibility of a standard or reference diphtheria prophylactic, based on the "purified toxoid, aluminum phosphate precipitated" preparation he describes. No reference standard for these products is presently recognized by government agencies in England or the United States.

Textbook of Anatomy and Physiology. By Catherine Parker Anthony, B.A., R.N., Instructor of Anatomy and Physiology, Lutheran Hospital, Cleveland, Ohio. Third edition. Cloth. $4. Pp. 614, with 208 illustrations. The C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1950.

This textbook is designed for use in nurses training schools where the two subjects anatomy and physiology are combined in a single course; it is also suitable for reference in high schools and for use in college courses. The style and arrangement are intended to facilitate teaching, and each chapter is provided with an introductory outline, a unit vocabulary, a concluding outline-summary and review questions. In addition, there are useful tables, a wealth of attractive illustrations and a good index.

Attention should be called to a medical superstition innocently perpetuated by the author on page 442, where it is stated that a person whose frenum linguae is "too short for freedom of tongue movements" is said to be tongue-tied and to have faulty speech. No speech defect of this sort is recognized in modern textbooks on speech correction; on the contrary, cutting of the frenum in the newborn may be followed by deformities that do entail speech defects. This was pointed out by McEnery and Gaines in 1941. On page 517 the author advises that in babies with undescended testes measures should be taken to bring the testes down into the scrotum. This recommendation should be replaced by the physiological facts noted by Drake in 1934, and by others as well, who found an incidence of more than 5 per cent of undescended testes in otherwise normal boys at birth, and who showed that in the overwhelming majority of these cases spontaneous postnatal descent occurred, sometimes as late as the age of 18 years. Drake concluded that the only case that should be considered a surgical problem is the bilateral one persisting to the age of 14 or the unilateral case with complications. It is hoped that these two errors, both capable of doing incalculable harm, will soon be eradicated from medical literature and will be corrected in future editions of this otherwise commendable book.

American Red Cross Home Nursing Textbook. Prepared under the Supervision of Nursing Services, American Red Cross. [Sixth revision.] Cloth. $1. Pp. 235, with illustrations. The Blakiston Company (Division of Doubleday & Company, Inc.), 1012 Walnut St, Philadelphia 5, 1950.

This book is an informative and helpful presentation of home nursing procedures. The instruction given is based on the assumption that the patient's treatments, other than emergency first aid, are ordered by a physician and that the general nursing care is under a physician's supervision or that of a professional registered nurse. The book is prepared primarily as a textbook for those who take the Red Cross home nursing course, but it will be helpful to others. It includes information on how to meet simple home emergencies, how to recognize some of the early signs of illness, how to provide simple nursing care for the sick and injured at home and how to help keep the family well. There are detailed instructions for carrying out many home nursing procedures. Selected additional references for those who wish to study further are mentioned. This textbook will be welcomed by its old acquaintances and the newer ones that it will make.

William Withering of Birmingham, M.D., F.R.S., F.L.S. By T. Whitmore Peck, M.P.S., and K. Douglas Wilkinson, O.B.E., M.D., F.R.C.P. Cloth. $4.50. Pp. 239, with illustrations. The Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1950.

This account of Dr. Withering's life and enterprises is no mere biography, in the conventional sense, but is more exactly a work of the heart. It is as though the authors desired to build a memorial to the man who had been a source of inspiration to them; and in so doing to instil in others a measure of the zeal they had derived from a study of his life. This gives one the feeling that the book is primarily oriented toward the student.

The authors have succeeded in compiling an interesting and moving account of the maturation and full realization of a man of genius, an account well documented and at the same time free from pedagogy. The book is replete with the letters, notes and case histories compiled by the famous physician of Birmingham, and the authors have chosen the best course—they let the man speak for himself—for William Withering was a man of vision, as a quote from "An Account of the Foxglove" will testify: "After all, in spite of opinion, prejudice, or error, Time will fix the real value upon this discovery (digitalis) and determine whether I have imposed upon myself and others, or contributed to the benefit of science and mankind."

The book contains a measure of interest for the layman, there being an absorbing description of the social milieu in which Dr. Withering lived and the relation of the doctor to his contemporaries. Throughout, this work is pervaded by the character of Dr. Withering, a man at once a great scientist, a good physician intimately concerned with the welfare of his patients and an active citizen of the community—a man who felt and shouldered the responsibilities entailed in being a physician.

Taxes and Economic Incentives. By Lewis H. Kimmel. Cloth. $2.50. Pp. 217. The Brookings Institution, 722 Jackson Place, N.W., Washington 6, D. C., 1950.

Realizing that the heavy revenues needed to finance greatly increased governmental expenditures can only be raised in an expanding economy, the author has prepared an analysis and appraisal of the principal taxes now employed from the standpoint of economic incentives. His study opens with a general discussion of taxable capacity in a free enterprise economy, which he defines as "the capacity to raise revenues without extreme interference with productive activity and the operation of the economy." The principal determinants of taxable capacity—the volume and composition of national income, the nature of governmental expenditures, the available methods of taxation and the reactions of people to tax burdens—are reviewed. Major emphasis is placed on the reactions of taxpayers. The four major taxes—income, sales and excise, property and payroll—are each examined in relation to four principal incentives essential to a dynamic and growing economy. These are the incentives to establish new businesses, for existing businesses to expand, to invest and to work. A discussion of incidence and shifting is presented in respect to each type of tax. Direct information on the reactions of the business community to specific taxes, which was obtained from a questionnaire sent to 1,000 manufacturing corporations, is also included.

This study indicates that the corporate income tax and the personal income tax are most detrimental to economic incentives. Decisions relating to the expansion of existing enterprises, particularly in the case of the small and moderate-sized firm, are considerably influenced by the corporate income tax, while the personal income tax has its greatest effect on the volume of savings available for investment. The incentive to work and the incentive to establish new enterprises seem to be influenced more by other factors than by taxes. Apparently, sales and excise taxes and property taxes have less effect on economic incentives than is generally believed. While the present rate of payroll taxes has not been found to be burdensome, an increase in this rate might have serious repercussions. Most important among the author's recommendations for an effective tax policy is a proposal for the coordination of the personal and corporate income taxes and the substantial reduction of the corporate income tax as such. His proposal is aimed at removing the present tax deterrents to business expansion without appreciably reducing any tax source. He stresses the importance of a balanced system of diversified taxes. With the events of the past few months and the necessity for even greater governmental expenditures, this book is particularly timely.

The Hormones: Physiology, Chemistry and Applications. Volume II. Edited by Gregory Pincus and Kenneth V. Thimann. Cloth. $12.50. Pp. 782, with illustrations. Academic Press, Inc., Publishers, 125 E 23rd St., New York 10, 1950.

This volume includes the bulk of studies in animal physiology and bioassay procedures relevant to endocrinology. Clinical endocrinology is relegated to a single chapter of 40 pages which, while well handled, of necessity must be sketchy. The chapters on physiology and chemistry are valuable sources of experimental evidence for present day theories of endocrine function. The bibliography is comprehensive. The series will prove most valuable to the serious student of endocrinology and those interested in experimentation in this field. The intent of the editors is a complete presentation of the subject at the research level. They have succeeded remarkably well in attaining this goal.

QUERIES AND MINOR NOTES

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

IMMUNIZATION OF DIPHTHERIA CONTACTS

To the Editor:—What is the accepted opinion regarding the use of passive immunization concurrently with active immunization in diphtheria contacts? Apparently those who object to active immunization being started at the same time that passive immunity is induced believe that one interferes with the other. Harold W. Conran, M.D., Suva, Fiji.

ANSWER.—It is generally accepted that active immunization of susceptible contacts of diphtheria cases is practical and effective when the first of two or three doses of antigen is given simultaneously with a prophylactic serum antitoxin. The empirical belief that the resulting protection from toxoid is neutralized to some extent by the passively acquired antitoxin and that the resulting protection from the passively acquired antitoxin is neutralized to a small extent by the toxoid has been confirmed by animal and human studies. However, the amount of interference of one by the other appears to be so small as to be negligible when optimum procedures are used.

The protection conferred by toxoid in animals and humans depends not only on the amount of toxoid used, the number of doses and the interval between doses but on the prior experience of the patient with diphtheria infection or immunization. Persons who have had such prior experience have their immunity mechanism sensitized so that they respond within a few days to a single small dose of toxoid and seldom require antitoxin. Persons not so sensitized need basic immunization, which requires much longer to develop. They require an effective primary stimulus before they can mobilize adequate amounts of antitoxin in the circulating blood. Such persons are of chief concern in considering the probable effectiveness of simultaneous active and passive immunizations. In such persons the primary stimulus induced by the first dose of toxoid is delayed and inhibited by simultaneous administration of prophylactic antitoxin. The protection following the second dose is increased either when the amount of toxoid in the first dose is increased or when the amount of antitoxin is decreased. Alum-precipitated toxoids give better response than plain toxoids, and alum-precipitated toxoids are more effective when given with a four instead of a two week interval between doses.

Available data indicate that during the eight week period following the second of two doses of alum-precipitated toxoid, which has been given with a four week interval to completely susceptible persons, those who receive 500 to 1,000 units of antitoxin at the time of the first dose are not as well protected as those receiving no antitoxin. However, after 14 weeks the protection in those receiving antitoxin is almost as good as in those receiving no antitoxin (Downie, A. W., and others, *J. Hyg.* 46:34 [March] 1948). The final slight difference in protection is of little consequence but can be obviated if one gives a third dose of toxoid or increases the interval between doses to six weeks. It is important that susceptible diphtheria contacts be kept under careful observation during the period when the passive immunity is low and the active immunity has not fully developed.

SENSITIVITY TO EMBALMING FLUID

To the Editor:—A mortician has a skin sensitivity to embalming fluid with a formaldehyde base. Is there an embalming fluid with other constituents available? Can the man be desensitized to formaldehyde?
L. R. Evans, M.D., Laramie, Wyo.

ANSWER.—The skin of many persons becomes inflamed by contact with formaldehyde fumes or solutions. Generally the skin of such persons is sensitive also to other substances or solutions, such as soaps. One so constituted must make adjustment to prevent or to minimize contact with these chemicals or substances. Morticians are supplied by manufacturers with embalming solutions that must comply in chemical content with state or federal regulations. Solutions with low formaldehyde content, or perhaps with no formaldehyde, are now available. Inquiry about these may be directed to the Champion Chemical Company, Springfield, Ohio; Dodge Chemical Company, Boston; Undertakers Supply Company, Westport, Conn., or Undertakers Supply Company, Chicago. There is no known procedure for desensitization against formaldehyde preparations.

EXCESSIVE PERSPIRATION FOLLOWING SYMPATHECTOMY

To the Editor:—A man aged 50 had a bilateral sympathectomy eight years ago for relief of Raynaud's disease of the fingers. Since then he has had excessive perspiration of the entire trunk of the body. This is a source of great embarrassment and retards his advancement in his company. Are there any drugs that might offer him relief?
W. F. Francka, M.D., Hannibal, Mo.

ANSWER.—Excessive sweating in hot weather is a common sequence of partial sympathectomy, because sweating is inhibited over the sympathectomized part of the body and the limited number of remaining functioning sweat glands have to work overtime in aiding dissipation of heat through evaporation. Whether this mechanism is important in this case cannot be determined, because the extent of the sympathectomy and circumstances of sweating are not stated. It is probable that the basic autonomic disturbance responsible for the original Raynaud's syndrome plays a role here. Excessive sweating, particularly of the axillas, palms and soles, commonly accompanies Raynaud's disease, and emotional stress seems to be an important factor in both the sweating and vasoconstriction of this disease. Furthermore, as Kuno has shown, mental and emotional stress influences sweat gland activity not only on the palms, soles and axillas but on the trunk. That emotional factors may be a contributory factor in this case is suggested by the fact that the patient allows the sweating to embarrass him socially and to retard his advancement in his company.

Drugs which block sweat gland activity are contraindicated where sweating is necessary for heat dissipation, as the body temperature would rise. Furthermore, the newer drugs which block the autonomic nervous system have side-effects and other disadvantages which preclude their continued use. If high environmental temperature is an important contributing factor, the installation of air conditioning or other cooling devices in the office and/or home should be considered. In any case, treatment should be directed toward getting the patient to accept the fact that sweating need not block his social and business progress.

RH ISOSENSITIZATION BY PREGNANCY

To the Editor:—A 25 year old quadrigravida is Rh negative, and her husband is Rh positive. The first child is six years old and well. The second child was delivered at eight months, lived six days and died. The third baby was delivered stillborn at six months. The patient is now three months pregnant. The result of the Wassermann test is negative. There is no history of venereal disease. How can I help this patient?
Alfred H. Hathcock, M.D., Fayetteville, Ark.

ANSWER.—The clinical story is strongly suggestive of Rh isosensitization by pregnancy, but the actual diagnosis depends on the results of tests for Rh sensitization. Blood specimens should be taken from the expectant mother and father and from the child and sent to a laboratory specializing in Rh tests. This laboratory will verify the Rh type of the husband and the wife and determine the Rh type of the living child. In addition, the laboratory will test the mother's serum in order to determine whether she is sensitized to the Rh factor. There are at least three possible results:

1. The tests may reveal that the original typing of the patient is incorrect and that she is actually Rh positive, or they may show that, although the patient is Rh negative, she is not sensitized to the Rh factor. In that case Rh sensitization could not be the cause of the neonatal death and the stillbirth, and some other explanation would have to be sought. The prognosis for the present pregnancy would then depend on the explanation found.

2. A stronger likelihood is that the laboratory tests would confirm the previous report that the patient is Rh negative and her husband Rh positive and, in addition, would show that the patient is sensitized to the Rh factor. Such results would support the surmise that the second baby probably died from erythroblastosis and that the stillbirth was also probably due to Rh sensitization. The prognosis for further pregnancies would then depend on the Rh type of the fetus. If the fetus is Rh positive, another stillbirth would be likely; if the fetus

is Rh negative, it would not be harmed by the maternal Rh antibodies. It would be helpful in this connection to determine whether the husband is homozygous or heterozygous for the Rh factor. A presumptive diagnosis as to genotype could be made by Rh-Hr typing of the husband. For example, if the husband belongs to any of the types Rh_1Rh_2, Rh_1Rh_1 or Rh_2Rh_2, he is probably homozygous for the Rh_0 factor, but if he belongs to type Rh_1rh or Rh_2rh he is probably heterozygous for the Rh_0 factor. It might be possible for one to determine the husband's genotype more exactly by typing his parents, if they are available, and also from the Rh type of the living child. Where the expectant mother is strongly sensitized to the Rh factor and the husband is homozygous for the Rh factor, a therapeutic abortion may be indicated, provided the pregnancy is not too far advanced. The abortion would be indicated not only because such a pregnancy would be futile but because it involves increased hazards for the mother, since toxemia and severe postpartum hemorrhage are not infrequently associated with hydropic stillbirths. In the present case, in which the pregnancy is already far advanced, the only recourse is to handle the problem as conservatively as possible.

3. A third possibility is that the neonatal death and stillbirth were not due to erythroblastosis but that now the patient has become sensitized to the Rh factor as an additional complication. In such an event attention should be focused primarily on the problem of Rh sensitization. If the tests indicate that the fetus in utero is almost surely Rh positive, it might be possible to save the baby by delivering it prematurely and treating it without delay by exchange transfusion. If, however, there is a possibility that the fetus might be Rh negative, the pregnancy should be permitted to go to term.

UNDESCENDED TESTICLE

To the Editor:—A 12 year old boy has bilateral indirect inguinal hernia, a small hydrocele on the left and an undescended testicle on the right, which could not be felt in the canal. He also has a large umbilical hernia. I gave him a preparation of chorionic gonadotropin (5,000 units) without success. I planned to repeat the course, but the child never returned. His mother recently told me that he is now taking tablets. What could these be? At what age should treatment with gonadotropins be started? If they do not correct the cryptorchidism, is a Torek operation indicated? Does this operation make a testicle capable of spermatogenesis?

Ervan L. Levine, M.D., Vandalia, Mo.

Answer.—Frequently a hernia cannot be felt in association with an undescended testis, although it is surgically present in a high percentage of cases. In the case of this 12 year old boy, it is generally the belief that 30,000 units of anterior pituitary-like hormone constitutes sufficient total dosage, given two or three times a week, 500 units per dose. This course should bring the testis down in about 25 per cent of patients at this age. If the boy is taking methyl testosterone orally, no effect should be expected. One must not forget that a fairly high percentage of undescended testes descend during puberty, from about 12 to 16 years. If given before the age of puberty, gonadotropins should hardly be expected to effect descent of the testis. These substances will hasten puberty in boys near that age, at 10 or 11 years. Furthermore, gonadotropic hormones will cause descent only in boys whose testes would normally descend at puberty. A course of gonadotropic substances at 10 years of age may prevent surgical correction. If descent does not occur, operation is indicated, with either the Torek or elastic traction suture method. Spermatogenesis depends in large measure on careful preservation of the internal spermatic vessels.

DIETHYLSTILBESTROL IN PREGNANCY COMPLICATIONS

To the Editor:—I would appreciate information on the effects of diethylstilbestrol. What quantity can safely be taken in any given period or through pregnancy?

Paul M. Egel, M.D., Chicago.

Answer.—Diethylstilbestrol is a synthetic estrogenic drug and has the properties of all estrogens. Its use in the treatment of the menopause and in other conditions associated with ovarian failure is not complicated by untoward symptoms other than nausea for a few days after the institution of treatment in about 5 or 10 per cent of patients. It has been recommended for the prevention and treatment of some pregnancy complications, such as habitual abortion, diabetes and the toxemias. Graduated amounts of this drug are administered, beginning with 5 mg. daily and increasing to 125 mg. at 36 weeks' gestation. The efficacy of this therapy in the prevention and treatment of these pregnancy complications has not been proved; such proof awaits well controlled clinical experiments. There is little evidence that these amounts of diethylstilbestrol are harmful to the mother or the baby. Women can tolerate huge amounts of this drug during pregnancy without the occasional nausea induced by even small amounts in nonpregnant persons.

POTT'S DISEASE

To the Editor:—I have been using streptomycin and paraaminosalicylic acid in a case of tuberculosis of the last lumbar vertebrae (Pott's disease). The patient is 25 years of age. The patient's general condition is satisfactory and there is no deformity of the spine. What are the recommended average doses, duration of treatment and prognosis?

Juan José Lahuerta, M.D., Corella (Navarra), Spain.

Answer.—There are many different possibilities of dosage for the patient mentioned. Since bone lesions are rather slow to respond, the dosage used has been higher than that for pulmonary lesions. At least 1 Gm. of streptomycin, or 1.5 Gm. of dyhydrostreptomycin, should be given for 60 to 90 days. Because the bacilli may become resistant, the tendency now is to space the dosage every other day, or even every third day, and give 10 to 15 Gm. of paraaminosalicylic acid for four months or more. The paraaminosalicylic acid must be given in liquid form, 3 to 4 Gm. four times a day, near meal time, as a full stomach helps to prevent nausea. If nausea develops and persists, it is sometimes necessary that treatment be stopped for a few days. Usually the patient tolerates the drug on the second attempt.

RECTAL TEMPERATURE OF INFANTS

To the Editor:—What is the normal rectal temperature of an infant?

J. J. Johnson, M.D., Las Vegas, N. Mex.

Answer.—There is probably no "normal" rectal temperature for infants of 1 to 12 months but rather variable temperatures within the boundaries of normal. If the bulb of the rectal thermometer is inserted 5 cm. into the rectum, a higher temperature will be registered than if it is inserted only 3 cm. In the newborn the heat-regulating system is unstable. The temperature curves may show a considerable daily variation, which may be due to bodily movements, ingestion of food and the external temperature, all of which may cause a rise or fall of rectal temperature readings. The less protected the baby, or the cooler the room, the lower the temperature may be. Premature babies, of course, show the most pronounced variation in temperatures. It has been noted that bodily exercise may increase rectal temperature readings in normal infants; restlessness and crying may also cause such a temperature rise. A certain group of children show a constant rectal temperature of somewhat higher readings than the normal average; these infants are often members of neurotic families. Oscillations in rectal temperature are so universal that they should be considered normal manifestations based on a somewhat unstable heat-regulating mechanism in young infants.

MIXED MATINGS

To the Editor:—The maternal grandparents of a young married woman are white. Her mother is also white, as are her maternal aunts and uncles. Her paternal grandfather is a Negro, his parents having both been Negroes. Her paternal grandmother is light in color, one of her parents having been a Negro, the other white. The young woman's father is light in color; two of his sisters are colored. She herself is white and is married to a white man whose ancestors were all white. Will the offspring of this union result in white or Negro children?

M.D., New York.

Answer.—In a comprehensive study of mixed matings in Jamaica, British West Indies, Davenport (Heredity of Skin Color in Negro-White Crosses, Publication 188, Washington, D. C., Carnegie Institution of Washington, 1913) found that in 22 matings similar to that of the young woman's father, namely, of light-colored fathers having one of four possible genotypic factors for skin blackness with white mothers having no factors for black, or light-colored mothers with white fathers, there were 56 children of the same color of the white parents, 80 children of the same color as the colored parents and 1 child darker than the colored parents. Presumably, the young woman is of the genotype similar to the above group of children having no factor for black (the Caucasian type) and cannot, therefore, contribute a factor for black to her offspring; neither can her mate, who is of a similar genotype. Davenport investigated the question of dark children being born to a pure-bred white married to a white extracted by mendelian segregation of alleles in mixed matings of progenitors. He found that the idea of "reversion to black" was mythical.

DIAGNOSIS OF PREGNANCY

To the Editor:—I would like to know what the present status is of the skin test for the diagnosis of pregnancy.

E. S. Olson, M.D., Racine, Wis

Answer.—There is no reliable skin test for the diagnosis of pregnancy, certainly none which can compare in reliability with the Aschheim-Zondek, Friedman, frog and many other tests.

ULCERS IN MOUTH AND THROAT

To the Editor:—A widower, aged 58, gave a history of ulcerations of the entire buccal cavity and throat for five months. On his first visit, he was so weak he was brought in with the help of the family. He said that he had not eaten anything for three weeks, having lived entirely on water, coffee and tea. I gave him livibron® (contains liver concentrate, thiamine hydrochloride, riboflavin, ferrous sulfate and manganese citrate), thiamine hydrochloride, vitamin B complex in large doses hypodermically and penicillin in sesame oil, 2 cc. daily. He has received these four drugs daily for 30 days. I also vaccinated him against smallpox, with a resultant "take." Since then he has been revaccinated twice without a "take." During the past month he has received typhoid vaccine, up to 3 cc., intramuscularly, which resulted in fever for periods of three or four days. Other medicaments given in full dosage include aureomycin hydrochloride capsules and troches and chloramphenicol. Phenindamine (thephorin®) was tried for five days. During the past three weeks he has received three roentgen ray treatments, consisting of 300 roentgen units, with 90 kv., 5 ma., at 8 inches distance, without additional filtration, given over a period of about one to one and one-fourth minutes. With the above therapy, he has gained 12 pounds (5.4 Kg.) and has been able to eat soft bland foods. The patient's teeth were extracted several years ago, but he does not use dentures. He does not smoke or chew tobacco. He has mild thrombophlebitis and recently had a small varicose ulcer of the leg, which cleared up. He has general arteriosclerosis with some varicose veins and, I suspect, mild cirrhosis of the liver. His buccal cavity, tongue and throat are still ulcerated, and the condition appears to remain unchanged. Is there any other therapy that might help the patient? Has he been overtreated?

H. W. Stevens, M.D., Wilson, N. C.

ANSWER.—The patient has received a great amount of treatment. The fact that he has improved in general suggests that the supportive therapy has been effective; the persistence of the oral changes indicates that therapy has not been specific. The future care of the patient should depend on diagnosis. If tuberculosis, stomatitis venenata and medicamentosa and other entities can be excluded, the diagnosis would seem to be either aphthous stomatitis or primary herpetic gingivostomatitis. These conditions are often not differentiated, though they should be because of their etiology and treatment. Blank, Burgoon, Coriell and Scott of Philadelphia have corrected previous misconceptions. Their studies on patients with recurrent aphthae failed to demonstrate the virus of herpes simplex; the virus was usually found in herpetic stomatitis. No specific herpes simplex antibodies were present in the aphthous cases. The cause of aphthous ulcers is unknown, and therapy is also uncertain. Recent reports indicate that aureomycin is of value, but it is possible that the condition was confused with herpes. The results from aureomycin were favorable in herpetic stomatitis. It is suggested that the diagnosis be made specific, if possible. The use of antibiotics and vaccine has perhaps been too brief, and further trial may be worth while, especially in the absence of immunologic studies. The use of smallpox vaccine should be continued for a series of eight vaccinations at 10 day intervals, whether or not there are "takes." Other methods of treatment have been mentioned in previous answers in this section (Feb. 7, June 12, July 10, Dec. 25, 1948; July 20, Sept. 24, Oct. 1, Dec. 24 and 31, 1949; March 25, 1950).

MYASTHENIA GRAVIS

To the Editor:—Please give what information you can about OMPA, which has been mentioned recently as a treatment for myasthenia gravis.

James W. Davis, M.D., Statesville, N. C.

ANSWER.—The designation OMPA denotes the phosphorus-containing insecticide octamethyl pyrophosphoramide, also known as pestox III. The compound was synthesized in Germany several years ago, and information regarding its pharmacology and toxicity may be found in the recent report of DuBois, Doull and Coon (*J. Pharmacol. & Exper. Therap.* 99:376 [July] 1950). Inasmuch as OMPA is a strong anticholinesterase agent, it is likely to be of value in the treatment of myasthenia gravis. Preliminary clinical trials thus far have yielded promising results. At present the drug is available only for investigational use.

PENICILLIN, STREPTOMYCIN AND AUREOMYCIN

To the Editor:—Is there any practical means of administering aqueous procaine penicillin and streptomycin in the same syringe? Is there any evidence which indicates incompatibility between aureomycin given orally and penicillin given intramuscularly?

Berryman Green, M.D., Laguna Beach, Calif.

ANSWER.—Therapeutic forms of aqueous procaine penicillin and streptomycin are available for dispensing in the same syringe and from the same container. There is no evidence that there is incompatibility between aureomycin given orally and penicillin given intramuscularly.

ULTRAVIOLET RAYS IN PULMONARY TUBERCULOSIS

To the Editor:—I was in my third year at medical school when I contracted pulmonary tuberculosis. I am home now and have a 50 per cent uniform collapse of my right lung. The doctors feel I will be able to start school this September. Would it be detrimental to use an ultraviolet lamp for the purpose of getting a sun tan. I have asked a number of physicians, but they do not agree. If ultraviolet rays are used to treat tuberculosis of the skin and tuberculosis of the bone, would they be objectionable for sun tan in a person with controlled pulmonary tuberculosis?

Daniel McIntire, Lafayette, La.

ANSWER.—Ultraviolet rays for the treatment of pulmonary tuberculosis is risky because of the danger of overdosage. If treatment time is gradually increased—a minute or two for a week, then another minute or two for the next week, and so on—no harm will result. The risk, however, is out of proportion to the gain. There are many effects produced by ultraviolet rays, both locally and systemically. Some of these effects are known, some are not. There is an effect on the pigment of the skin, an inflammatory reaction where the blood cells are increased, and an increase in humoral substances, some of which are toxic. There is a wide difference between pulmonary tuberculosis and tuberculosis of the skin. Cutaneous tuberculosis is generally superficial and localized in the skin. Rarely does it spread beyond the skin. A lesion can be treated without much risk of spreading. In lung lesions the toxic agents in large dosage may cause a break in the cellular defense of the soft lung lesion, resulting in a spread to other parts of the lung or body. The effect is like that of any toxic agent, including burns.

FEVER THERAPY IN ASTHMA

To the Editor:—Please give information on fever therapy in cases of asthma.

M.D., Pennsylvania.

ANSWER.—The salutary effect of acute febrile disease on allergic manifestations has been known for centuries. Chronic and intractable asthma frequently becomes more completely relieved by intercurrent nonrespiratory infection than by almost any other means. It is not certain whether the elevated temperature or the conditions causing it (tissue destruction, bacterial substances, hormone production) are responsible for the benefit. Typhoid vaccine, injection of colloidal sulfur and malarial therapy have been used in the past. Fever produced by high frequency currents (diathermy) was used a number of years ago (Feinberg, S. M.; Osborne, S. L., and Steinberg, M. J.: Sustained Artificial Fever in the Treatment of Intractable Asthma, *J. A. M. A.* 99:801 [Sept. 3] 1932). More recently a pure carbohydrate constituent obtained from certain bacteria and known as pyromen® has been used to produce fever. An intravenous injection of 1 to 50 gammas will produce fever and other symptoms. While any of the above methods may relieve asthma, most of them are not without danger. They must be used with great caution, and the results are apt to be temporary.

COMPENSATION IN PARTIAL LOSS OF VISION

To the Editor:—What modification of the standard percentage of visual efficiency or loss is made in the case of slight impairment affecting one eye when vision in the other eye has already been impaired from preexisting and nonrelated disease? What modification is made depending on the visual level of the other previously impaired eye? The case in point is one in which the right eye carried a vision level of counting fingers owing to a previous disease. Years later retrobulbar neuritis developed involving the left eye, reducing vision to a 20/70 level after correction, with a permanent residual scotoma involving the central fixation area. This condition is compensable under the terms of the patient's private health and accident disability insurance. The percentage loss in visual efficiency according to the American Medical Association standards in this case would be about 33 to 35 per cent. But I wonder whether the percentage loss should not even be greater for a person whose vision in the other eye was practically serviceable previously. It seems to me that a 30 per cent loss in his only remaining eye is a far greater tragedy to him and actual disability than would be the case if the remaining eye had a normal level or a more moderate impairment. I think the standard percentage for visual loss in a case like this should therefore be modified, but I am not in possession of any tables showing what modification is reasonable. I would appreciate enlightenment on the subject.

H. Weldon Wilkinson, M.D., San Jose, Calif.

ANSWER.—Tables reducing disability to definite percentages are useful as a guide in some cases but inadequate in cases such as this. After the evidence is presented by the plaintiff and the defendant, the judge has to decide and usually allows much more than the percentages suggested by the Committee on Compensation of the American Medical Association. Different occupations require different degrees of visual acuity; what might be a serious loss to one would be only a moderate loss to another, although algebraically they might be equal.

PIGMENTATION FOLLOWING TREATMENT FOR ACNE

To the Editor:—A Negro woman who is being treated for acne of the face now has darker pigmentation of the treated areas. Is there any safe bleaching agent that may be used on the patient's face? The acne has improved.

M.D., Ohio.

ANSWER.—Melanosis following actinic ray application may occur in any racial group. Such occurrence has been observed frequently after one treatment, but it usually becomes pronounced after the third. The sulfur content of the skin and the use of sulfur or sulfur-like preparations either before or during therapy seem to be the chief contributing factors. One may prevent or alleviate the condition by (1) prohibiting or reducing the intake of sulfur-containing foods during the treatment period, (2) carefully and thoroughly cleansing the skin before treatment and (3) refraining from the use of sulfur-containing preparations for the duration of treatment. If left alone the melanosis will disappear in six to 12 weeks; mild skin peeling will hasten the process. An ointment of 2 per cent salicylic acid and 10 per cent ammoniated mercury in a greaseless ointment base is satisfactory. This application is to be made and removed immediately when tingling is noticed and then reapplied on the following day. Treatment should be repeated until desquamation occurs.

PRUNE JUICE AS A CATHARTIC

To the Editor:—I have a sample of prulose®, which apparently contains 2 grains (0.12 Gm.) of dehydrated prune concentrate, 6 grains (0.40 Gm.) of methylcellulose and 1/63 grain (1.03 mg.) of diacetyldioxyphenylisatin. It was stated that this last-named drug is the cathartic agent in prunes. I would appreciate knowing whether this drug is prepared synthetically or by the processing of prunes. If it is not the cathartic principle of prunes or prune juice, what might it be?

Walter A. Fansler, M.D., Minneapolis.

ANSWER.—According to Emerson (*Proc. Soc. Exper. Biol. & Med.* 31:278, 1934) water extracts of prunes possess certain chemical and physiological properties similar to dihydroxyphenylisatin. Emerson also found that, while diacetyldioxyphenylisatin (isacen) had effects similar to prune extracts on the isolated gut, the compound, unlike prune extracts and dihydroxyphenylisatin, did not give a positive reaction in the ferric chloride test for phenolic groups. Diacetyldioxyphenylisatin, a phenolphthalein derivative, was synthesized by Guggenheim in 1925 in a search for a more effective cathartic agent than phenolphthalein. He found it to be less irritating to the stomach than the parent nonacetylated compound. It was accepted by the Council of Pharmacy and Chemistry in 1926 but omitted in 1940 because of lack of clinical evidence that it possesses any demonstrated superiority over phenolphthalein and because it was more expensive than phenolphthalein.

IMMUNIZATIONS IN OLDER PERSONS

To the Editor:—Preparatory to traveling to South America, a man and his wife asked me about typhoid, paratyphoid and typhus vaccination. Are there any contraindications? The man is 60 years old, had typhoid when he was 12 and is a mild diabetic. He has arteriosclerosis, blood pressure of 160/95 and retinopathy which has been stable for several years. His wife, 65, had a mild cardiac attack several years ago, with residual low cardiac tonus.

M.D., New York

ANSWER.—It is unlikely that a 60 year old man who has had typhoid would experience another attack and he might have an unpleasant reaction if given typhoid vaccine. It seems reasonable that this man, in his present condition, not be subjected to any immunizing procedure which is not urgent. Although typhoid is not common at 60 to 65 years of age, it is advisable to afford the wife protection. If the intracutaneous method is used, the possibility of severe reactions is lessened. The couple should not be denied protection from typhus if they are going to a locality where typhus is either epidemic or endemic.

VITAMIN C AND CATARACTS

To the Editor:—Is there any scientific evidence to show that the continuous and prolonged oral use (more than one year in the case in question) of 300 mg. daily of ascorbic acid can produce opacities of the crystalline lens?

M.D., New Jersey.

ANSWER.—There is no clinical or experimental evidence that human beings experience any toxic effect from vitamin C given in the dosage mentioned. Vitamin C plays an important part in the nutrition of ocular tissues. The healthy lens is particularly rich in this vitamin, while totally cataractous lenses contain little or none. There is evidence that vitamin C has no direct bearing on the experimental production of cataract but no evidence that an excess of it contributes to the development of cataract.

VAGINAL PROLAPSE

To the Editor:—What is the incidence of vaginal prolapse following vaginal hysterectomy for uterine prolapse in general and particularly after Heaney's operation for prolapse? What are the best operative methods for vaginal prolapse following vaginal hysterectomy?

I. Andrussier, M.D., Philadelphia.

ANSWER.—Vaginal prolapse after vaginal hysterectomy is rare. Veenboer and Kooistra (*Am. J. Obst. & Gynec.* 53:936 [June] 1941) followed 104 cases of vaginal hysterectomy from 18 months to four years and found no cases of vaginal prolapse. However, Rhoads and Zeit (*Am. J. Obst. & Gynec.* 51:533 [April] 1946) followed 385 vaginal hysterectomies according to the technic of Weir and found four cases of prolapse of the vaginal vault (2.08 per cent). Some gynecologists have performed several hundred vaginal hysterectomies without the occurrence of prolapse of the vagina, and this is true of the Heaney technic; but prolapse of the vagina following vaginal hysterectomy is a definite possibility. Vaginal prolapse must be differentiated from enterocele.

There are two ways of attempting to cure prolapse of the vagina, one of which employs the abdominal route and the other the vaginal route. The abdominal operations of suspending the vagina to the abdominal wall are generally not satisfactory. Much better results are obtained by an extensive vaginal plastic operation including suture of the posterior vaginal fascial layers and the building up of a strong levator sling and perineal body. In very old women partial or complete colpocleisis may be done.

ARTHRITIC CHANGES OF OLD AGE

To the Editor:—Is the use of desoxycorticosterone acetate warranted in the treatment of the hypotrophic arthritic changes of old age in which the cause is obscure?

M.D., Mississippi.

ANSWER.—Rheumatologists are almost unanimous in their opinion that desoxycorticosterone acetate does not exert a beneficial action on any type of arthritic process. Furthermore, its potential hazards in hypertensive and cardiac patients, because of salt and water retention, must not be overlooked. Because of the many cardiovascular and renal changes in old age, desoxycorticosterone acetate must be used with caution when indicated.

POSTNASAL DRIP

To the Editor:—A patient with chronic sinusitis of many years' duration has nocturnal postnasal drip. He awakens from sleep to expectorate the material about twice nightly. Being awakened he voids. This nocturia was ascribed to prostatic hypertrophy. I considered the nocturia as pseudonocturia, since no prostatic enlargement was found. I prescribed 50 mg. of diphenhydramine hydrochloride before retiring, with splendid response. Occasionally, the patient forgets to take the drug and his sleep is again interrupted as aforementioned. The patient believes that he has become addicted to this drug. I reassured him that this drug, in the dosage given, is not habit forming and that it would not cause "liver damage."

M.D., New York.

ANSWER.—While diphenhydramine hydrochloride is the most sedative of the antihistaminic drugs, as yet there are no reports in the literature of addiction to the drug because of this effect. Long term use of any sedative may lead to dependence. Experimental evidence indicates that detoxification of diphenhydramine probably occurs in the liver, spleen and kidney, with the liver playing the primary role. Chronic toxicity studies have failed to disclose definite liver damage due to this drug, but effects on the hemopoietic system have been noted.

HAMSTERS FOR CULTURING TUBERCULOUS MATERIAL

To the Editor:—In *The Journal* of July 22, 1950 (page 1127) in response to a query as to the possibility of using hamsters instead of guinea pigs for inoculation of possible tuberculous material, it is stated, ". . . the culture is much cheaper and in a number of ways more *efficient* and direct." I feel that many of the men dealing with tuberculosis will not agree with that statement.

The culturing of sputum or gastric contents may be a bit cheaper than inoculating a guinea pig, but I believe it is far less reliable. Cultures are *difficult to grow* and must be interpreted by experienced laboratory personnel. I find that about 5 per cent of gastric lavages reported as being negative on culture are positive on guinea pig inoculation. This *is especially true in* cases in which there has been adequate collapse and chemotherapy. Of some dozen veterans recently discharged from a *Veterans Administration* hospital, all of whom have had literally dozens of negative gastric cultures, three have been found to have *negative* cultures, but guinea pig inoculation of the same specimen was positive. In a matter as vital as this, a small additional expense should not stand in the way of certainty of ruling in or out the *presence* of active tuberculosis or of giving the patient a false sense of security.

MISCONCEPTIONS IN UROLOGY

Chairman's Address

EDWARD N. COOK, M.D.
Rochester, Minn.

As the years pass and the physician practices medicine in a particular field, he cannot help acquiring not only actual knowledge, if he has the ordinary intelligence and ability to grasp ideas and is ever on the alert with his eyes and ears open but his mouth shut, but also many concepts which have a philosophic as well as a scientific background. He will learn much of the art of medicine that today, in many instances, has been relegated to an insignificant place in the life of the physician. He will and should learn much of the proper way to live with his fellow man and his colleagues in medicine. He will acquire a broadening of his perspective, a greater ability to evaluate situations and a better sense of judgment. Unfortunately, he may also develop a dogmatism which at times will only lead to a narrowing of his perspective, a lessening of his sense of values, and the committing of errors in judgment. It is impossible for a modern physician to remain confined within his own special field and yet expect to practice medicine for the greatest benefit of the patient. Drs. W. J. Mayo and C. H. Mayo years ago saw the need for travel and study; they were always ready and eager to accept new studies if they were to the patient's advantage.

THERAPY

Today there are certain conditions that urologists are called on to treat and that at times, in my opinion, are not properly treated. Misconceptions about causation, interpretation of observations and modes of treatment have led to poor results which need not have occurred if a more careful interpretation of the available data had been made. I shall mention a few of these conditions.

Infections of the Urinary Tract.—Today, in the management of infections of the urinary tract, there is danger of the carelessness engendered by overconfidence in the seemingly adequate chemotherapeutic and antibiotic compounds easily available to the urologist. Too often a prescription is written for one of the newer and more expensive compounds when a few pills of one of the old established remedies would be of equal therapeutic value and would cost only a fraction as much as the newer drug. Carroll, Herrold, Finland and others have repeatedly urged that a complete inventory of any problem of infection be made before treatment is instituted. For many years I have stressed the need of recognizing any associated pathologic entity which would tend to lessen the efficacy of one or the other of these therapeutic agents. For instance, one cannot hope to sterilize urine in the presence of calcareous obstruction or a similar lesion.

Urethral Infections.—Another group of infections which I believe have been inadequately managed are those involving the urethra in both the male and the female. Urethritis in the male many times is a result of overtreatment. Studies of the associated discharge will reveal this. In his desire to help the patient a zealous physician may, by the too frequent and perhaps unnecessary use of irritating solutions and sounds, prolong and even aggravate the condition. Inflammation of the female urethra has been treated poorly. Overtreatment is most common. The proper diagnosis has been missed many times because of failure to examine a properly obtained specimen of urine and because adequate cystoscopic evaluation with the direct-vision instrument was not done. Time and again the antibiotic agents, with their high cost and sometimes difficulties of administration, have been used with the only benefit accruing to the drug house which sold them.

Conditions Based on Neuroses.—As in any branch of medicine, the urologist will see a considerable number of patients who have complaints referable to the urinary tract but without organic basis. Such neuroses may be divided into those associated with the urinary bladder and those associated with the sexual act.

Urinary Bladder: In many instances frequency of urination, when it is not accompanied with nocturia or dysuria in any form and when results of urinalysis are essentially normal, may well have a basis in habit. Each year patients are encountered who complain of this condition and who actually have received too much local therapy as well as chemotherapy without benefit. Simple understanding of such a patient's psychological background, with a careful and detailed explanation to the patient, enlisting his cooperation in gradually making the bladder hold more urine, will relieve the complaint.

Sexual Disturbances: The greater number of neuroses in urology are related to sexual disturbances Too often those regarded as leaders in the medical field are unwilling to take the time to sit down with these poor unfortunates and really explain why they have such a neurosis. Practically every patient who complains of sexual difficulties does so because of some functional disturbance. In many it is fatigue, mental or physical, and in a great number it has a basis in worry.

From the Section on Urology, Mayo Clinic.

Read before the Section on Urology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 29, 1950.

Such apprehension and concern may arise from past indiscretions. Patients may be apprehensive of the future. They may be afflicted with mother-in-law trouble. These are but a few of the varied stories that all urologists from time to time can extract from such patients. In fact, one seldom fails to elicit such a story in any individual case. The only cure for these disturbances lies in a sympathetic and understanding consideration by the urologist of the condition of each patient. Sometimes it may seem wiser to turn the problem over to the psychiatrist, who undoubtedly is better trained in some of the details and analyses of such conflicts. I do not agree to such a course. I say this with all respect to my colleagues in psychiatry and mainly because many of my patients have said to me, "They tried to send me to a psychiatrist, but this trouble is not in my head; it is in my sexual organs."

Urologists should not become so concerned with the glamor of the surgical aspects of their specialty that they lose sight of the opportunities to help a definite group of persons—those who in the long run will be most grateful patients. Hormonal therapy has been of absolutely no value in this group of cases. Any benefit resulting from the administration of the androgens or the estrogens is, I am sure, purely psychic.

Enuresis: The complaint of enuresis often is presented to the urologist when he sees children and adolescents. The literature discloses that urologists are writing about a number of local lesions in the urethra and vesical neck which are held to be responsible for enuresis in these persons. Phimosis, urethral stricture, inflammation of the urethra, verumontanitis and the like all have been offered as the etiological answer to enuresis. However, if the subject is investigated from the standpoint of the psychiatrist, it will be seen that in any patient who has this condition evidence of conflicts can be found. Moreover, such an investigation might bring about the conviction that because of some psychiatric disturbance in the patient this unfortunate complication has developed. I believe that both the urologist and the psychiatrist would be definitely wrong in such an interpretation of the cause. In my experience and that of my colleagues seldom if ever has any lesion been found in the urethra to which we could attribute irritation that would cause enuresis.

As I have examined the psychiatric records of a number of patients such as these, my impression has been that the greatest conflict lies not within the child but within the parents. Invariably, the conflict that the psychiatrist describes as the "cause" of enuresis has developed after the enuresis has been present for months and even years. Each urologist should pay particular attention to the next patient who voices such a complaint. I believe the solution to the entire problem will be obtained if one question is asked: "What kind of sleeper is this patient?" Frequently the answer will be, "You could shoot a cannon off in his room and he would not wake up."

I believe these persons achieve such deep slumber that even their subconscious processes, which normally keep the muscles controlling urination in a state of contracture, are unable to provide the proper stimulus to continue this contracture. By taking some sort of mild stimulant which will diminish their deep slumber, most of these patients, in my experience, respond well and eventually correct their difficulty. I have prescribed 3/8 grain (25 mg.) of ephedrine sulfate to be taken at bedtime for one week to two weeks. Invariably this will enable the patient to remain sufficiently aware of his full bladder without actually disturbing his sleep, so that the muscles remain contracted and there will be no loss of urine. As the patient attains some confidence in himself, he gradually finds that he can hold his urine while he is asleep. The dose of ephedrine sulfate can then be taken every other night for a period of a few weeks and then less often until use of the drug is given up entirely. Such a method of therapy frequently is supplemented by the provision of a period of rest at noon so that the patient will not become too fatigued and also at times by awakening the patient at midnight and having him empty his bladder. I am certain that it is only in rare instances that any local lesion in the urethra contributes to enuresis, and I am equally certain that the conflict which the psychiatrist describes, and to which I have referred, is the result of the disease and not the cause of it.

Another condition occurring in children, specifically, recurrent infection in the male infant and small child, has been ascribed to the congenital deformity known as "posterior urethral valves." These folds of tissue, extending longitudinally from the vesical neck to the verumontanum, too often have been held accountable for recurrent infection and obstruction of urine. At the Mayo Clinic it is rare to find that such a lesion is present. Inadequate and improper chemotherapy is the usual cause of recurrent infection in such patients. If obstruction is present, it is much more likely to have been caused by contracture of the vesical neck.

ATTITUDES OF THE UROLOGIST

Within the past decade I have noticed two particular instances of what seems to me a most selfish attitude on the part of the persons concerned. Many urologists are actively engaged in teaching programs for the undergraduate and the graduate student in urology. No one would deny that he is pleased to occupy a position of guidance in medical education. In such a relationship, however, the student necessarily must be content with a subordinate position, as has been true from ancient times. In the instances to which I have referred, two well-known practitioners were concerned. They were outstanding men, who had contributed importantly to their specialty as well as to organized medicine. However, when the time came for the entry of other young practitioners into their communities, they employed what must be called reprehensible measures in an attempt to keep out these younger men. Why is this? Are they so unsure of themselves that they fear fair and ethical competition? If such be the case, their communities certainly need the new men.

Many times the giving of proper help and encouragement to a young man just starting out may and usually will lead to a relationship advantageous to both parties concerned. There should be much satisfaction to the older man as he reaches retirement if he can point to someone who is doing well, about whom he can say, "I helped train him and assisted him when I could as he started his practice."

The final misconception which I should like to mention concerns an ever growing attitude on the part of the graduate student in urology toward what in his opinion constitutes the practice of urology. In the past ten years there has been a noticeable change in this attitude. The change has been for the worse, in my belief. Today, to use the words of Dr. N. G. Alcock of Iowa City, an outstanding urologic teacher, "they are knife-happy." These graduate students seem to have little interest in such trivial measures as passing a catheter without hurting the patient or introducing infection. Their attitude is that anyone can pass a sound or a cystoscope, that transurethral procedures are relatively easy and that their use can be learned at will during the period of surgical training. Deliver me from such misapprehensions.

Why is such an attitude so prevalent today? It can be noticed virtually everywhere. Many of my friends scattered the country over have told me they are encountering the same thing. The answer, I believe, is obvious. In respect to training for specialty recognition, qualification for membership in societies, and presentations at meetings, the surgical aspects of urology have seemed to be stressed preponderantly. I would be the first to extol proficiency in urologic surgery, but at the same time I certainly cannot agree that it holds the supreme position some of my colleagues would lead me to think it should have. The art of medicine is far too profound and complex to be symbolized simply by the act of holding a scalpel. A urologist must be trained in all the phases of the specialty: diagnosis, instrumentation, various types of local therapy and surgery, both closed and open.

OPHTHALMOLOGY AT THE MIDCENTURY

Chairman's Address

A. RAY IRVINE, M.D.
Beverly Hills, Calif.

As we come to the halfway point of the twentieth century, it is appropriate to consider, in long range terms, the trends in ophthalmology during the last half-century and the scientific, socialistic and economic changes that are determining its future. The last 50 years have been characterized by tremendous progress in the basic sciences, in the development of medical research, the organization of teaching facilities and in the availability and utilization of these accomplishments by virtue of superior transportation and communication. In ophthalmology, the development of the ophthalmoscope and the slit lamp and the progress made in physiology have enabled the clinician to correlate his observations with the microscopic changes in diseases affecting the eye and have been largely responsible for the great advances made during this time.

INFLUENCE OF BASIC SCIENCE

More and more, a direct application of the basic sciences, such as physics, biochemistry, bacteriology and pathology, will be made in diagnosis and treatment. An example of such an application is the clearing of corneal edema by the instillation of glycerin, a phenomenon arising from knowledge of semipermeable characteristics of the endothelium and epithelium. Phillips Thygeson has correlated the clinical signs of many external diseases with the bacteriologic flora of the conjunctiva and cornea and with their histopathology. His technics, originally thought by many to be impractical, have proved to be office procedures easy to perform and extremely applicable to the immediate treatment of the patient. These are but two of many direct relations between basic science and ophthalmology.

In like manner a close alliance is occurring between ours and other medical specialties. Indeed, it becomes apparent that in this age of specialization, when ophthalmology itself is evolving into subspecialties of medical ophthalmology, neuro-ophthalmology, ophthalmic surgery and ophthalmic pathology, the traditional distinctions among these branches become indefinite. It has become as important for the ophthalmologist to understand cell metabolism and body fluid physiology as it is for the internist to understand them. This dependence on fundamental knowledge and its application and the increasing interrelation between the various branches of medicine fosters specialization to a degree far greater than practiced today. It becomes apparent that ophthalmology encompasses a field so large that one person cannot hope to cover it, which suggests that in the future specialization will increase. There will probably be more emphasis on and attention paid to group practice, each man within the group having his particular interests and talents, all of which will be necessary to best care for the patient's needs.

SOCIALIZED MEDICINE

Such specialization and accomplishments are best fostered by a social system of free enterprise. For advancement in any field, there must be strong and able persons or groups competing with each other, yet with such an interchange of ideas that they are all operating effectively, to each other's advantage. Any one organization, whether that organization be a government organization or a research institute, must never be allowed to dominate the research or other activities of these persons or groups.

The scientific, critical mind must have unhampered opportunity for free expression and exchange of ideas in order to produce the greatest intellectual wealth. Such opportunities are not available under the domination of a remote socialistic bureaucracy. The intimate and confidential relation between physician and patient must be encouraged and preserved, whereas under the socialistic program this relation is severed, and the professional responsibility becomes nebulous, advice unspecific and skill more or less disinterested. Commercialism enters the door while true professionalism seeks the exit.

We may divert the trend away from socialism by encouraging voluntary health insurance, wherein the patient realizes that there are obligations as well as benefits and thereby does not lose control of his personal welfare. We may divert it by strengthening the laws that provide government aid to that small proportion of the population who cannot afford to pay medical bills or insurance premiums, but our influence will not be heeded unless the sick have confidence in the physician they choose and look to him as their sympathetic adviser and wise professional counselor. Your attitude toward every patient you see, in your office, in his home or in the hospital, is influencing the trend and determining the ultimate outcome. If yours is an attitude of concern only for the welfare of the patient, there will never be a system of socialized medicine in this country. The absolute attainment of this attitude, like religion, is not acquired without effort. It must be ever taught, practiced and publicized.

Read before the Section on Ophthalmology at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 28, 1950.

Because of the tremendous increase in the population of the United States and the fact that the span of life has been lengthened 20 years in the last few decades, the blind program has become one of great economic concern to us all. According to the National Association for Prevention of Blindness, there are approximately 280,000 blind men and women and children in the United States. This burden to the taxpayers, during the past decade (in this state alone), is approximately $40,000,000. The federal government in 1948-1949 paid over $40,000,000 in aid to the blind. In the animal kingdom blindness means death; in the human race blindness means dependence, and dependence means burden economically and spiritually. A great deal has been accomplished in the rehabilitation program in the few states in which it has been established. In five states where some sort of rehabilitation organization has been instituted, noteworthy progress has been made in the last few years. In these five states about 3,000 blind had sufficient vision restored through surgical intervention and medicine to be removed from the blind aid category.

In this state $85 a month is paid to the blind. In several other states it is much less, but it will average at least $50 per month per person. If we consider an average of $50, approximately $2,000,000 yearly has been saved to the taxpayer by rehabilitation of the blind. How much could be accomplished if these savings through restoration of vision could be allotted to research associations and institutions for the prevention of blindness and the treatment of the blind. Less than $1,000,000 a year is spent in the universities and laboratories in the United States for eye research.

CONCLUSION

If all members of this association could become more vitally interested in the programs of the blind in all the states, the accomplishments would be astounding. During the past 50 years we have seen greater achievements than were accomplished under a few great leaders in the previous century. During these last 50 years, many more great leaders have undoubtedly left their footprints in the field of progress. I foresee from among this great organization many younger ophthalmologists who will carry on our great work and leave a lasting imprint of still greater and more far reaching accomplishments in the conservation, improvement and restoration of human eyesight.

9730 Wilshire Boulevard

Rays Beyond 70,000 Feet Altitude.—A new component has been discovered in these regions, the heavy nuclei rays. They have a relatively small penetrating power and do not occur therefore below 70,000 feet. They consist of atomic nuclei of higher atomic numbers which are stripped of all their orbital electrons. They carry the tremendous amount of kinetic energy of more than 2 billion electron-volts per atomic number. Their specific ionization is much higher than any other hitherto observed value. The mechanism of absorption in matter is of the same type as that of alpha particles but magnified by a factor of 1,000. Their range in living tissue reaches values of 10 centimeters in comparison of 50 microns for alpha particles. An estimation of their possible biological action indicates that they might represent a serious hazard to health.—Hermann J. Schaefer, Evaluation of Present-Day Knowledge of Cosmic Radiation at Extreme Altitude in Terms of the Hazard to Health, *The Journal of Aviation Medicine*, October 1950

RADIOACTIVE DIIODOFLUORESCEIN IN DIAGNOSIS AND LOCALIZATION OF CENTRAL NERVOUS SYSTEM TUMORS

LOYAL DAVIS, M.D.
JOHN MARTIN, M.D.
MOSES ASHKENAZY, M.D
GEORGE V. LeROY, M.D
and
THEODORE FIELDS, B.S
Chicago

Radioactive diiodofluorescein has been utilized in the study of 200 patients with the diagnosis of a space-occupying lesion of the central nervous system. We have correlated our observations with the preoperative clinical diagnosis, electroencephalography, pneumography, angiography and surgical and autopsy observations We have made postoperative and postirradiation tests and, finally, we have correlated all these studies with the histopathological characteristics of the tumors. The results indicate that this radioactive isotope dye test is a valuable diagnostic adjunct in neurosurgical problems not only because of its high degree of accuracy in determining the presence of brain tumors but also because of its relatively precise focal localization. The possibility of prognosticating in a general fashion the relative degree of cellularity and vascularity of the tumor also appears to be feasible.

Fluorescein was believed to have a special affinity for tumor cells as early as 1911, at which time Wasserman, Keysser and Wasserman[1] used tetrabromofluorescein (eosin) as a vehicle to carry toxic selenium to the tumor for chemotherapeutic purposes. In 1929 Copeman, Coke and Gouldesborough[2] and in 1931 Copeman[3] used sodium fluorescein, both topically and intravenously, in conjunction with high voltage roentgen therapy or radium, in the study and treatment of tumors of the breast and bone. However, fluorescein was used primarily in the study of capillary permeability in diseases of the central nervous system, in the study of the blood-aqueous humor barrier and in circulation time studies.[4] Experimental studies with other vital dyes

on neoplastic growths in lower animals, by Ludford,[5] by Duran-Reynals [6] and by Hess [7] seem to indicate that foreign dyes localize selectively in cancer tissue, not in the cancer cell itself but in the intercellular stroma, probably as a result of the altered permeability of the stromal blood vessels. Boyland and McClean [8] and Duran-Reynals stated that this abnormally high permeability leading to the escape of dye may be increased by the "spreading factor" of cancer. The latter author also noted that localization of dye in tumor tissue takes place rapidly, within one-half hour after intravenous administration and mainly in the active nonnecrotic portion of the tumor.

Stevens and his colleagues [9] studied the distribution of radioactive iodinated trypan blue and other dye preparations in tumor-bearing mice and noted that tumor tissue showed concentration of radioactivity several times higher than skeletal muscle or skin but much lower than the liver, spleen and kidneys. We also have noted the intense relative concentration over the liver, spleen, kidneys, lungs and thyroid, which may be the result of their reticuloendothelial tissue content and relatively high degree of vascularization. Broman [10] studied vascular permeability in man by supravital staining with trypan blue and noted that the blood vessels of brain tumors lack the special permeability function of the blood-brain barrier. Zahl and Waters [11] studied the localization of acid dyes, other than fluorescein, in animal tumors and reached the conclusion that the dye seems to localize selectively in neoplastic foci, dependent on a factor associated with a local increase in capillary permeability to the dye. They noted that Evans blue accumulates much more heavily in, and is retained longer by, malignant tumors and metastases than benign tumors. They also emphasized that acid dyes localized not in the tumor cells but in the surrounding stroma, and that later they appear within the macrophages about the edge of the tumor and in the reticuloendothelial system of the liver and spleen.

A recent experimental study by Shapiro and Landing [12] on the significance of the distribution of fluorescein in SA 180 mouse tumors revealed that in 12 minutes there was a uniform, well defined fluorescence in the tumor, with concentration diminishing to zero in the other animal tissues except those which are the normal routes of excretion for the dye . At time intervals after two to three hours fluorescence was observed predominantly in the areas of necrosis. We might expect a glioblastoma or metastatic carcinoma to retain fluorescein longer in its necrotic areas and thus yield relatively high differential counts even at the third and fourth hours. This has been noted in our radiodye localization studies. In 1940 Gifford [1b] demonstrated that fluorescein is an acid-diffusible dye, about 40 per cent of which is bound to blood proteins and is not diffusible, unless the permeability of the capillaries is altered. The other 60 per cent is found in the body fluids in direct proportion to its concentration in the blood. It is rapidly excreted by the kidney and by the salivary and sweat glands. It was not until 1947 and later that Moore and associates [13] first used fluorescein as an agent in the differentiation of normal and neoplastic human tissues. In an initial report on 15 patients [14] he demonstrated the clinical usefulness of the I^{131}-labeled fluorescein in the diagnosis and localization of brain tumors. Tabern [15] developed a method for the production of stable diiodofluorescein that contained no free I^{131} or other iodinated fluorescein compounds.

TECHNIC

Stable radioactive diiodofluorescein is dispensed in a sterile 8 to 10 per cent solution, the specific gravity of which is approximately 1.5 times 10^{-5} per cent. Approximately 1.1 millicuries of the radioactive dye is injected intravenously, using appropriate radioisotopic precautions to prevent contamination of the skin of the patient and operator. The uptake in the brain is then determined by external counting with the aid of a single channel differential radiation localizer. This radiation detection equipment consists of four major components (fig. 1):

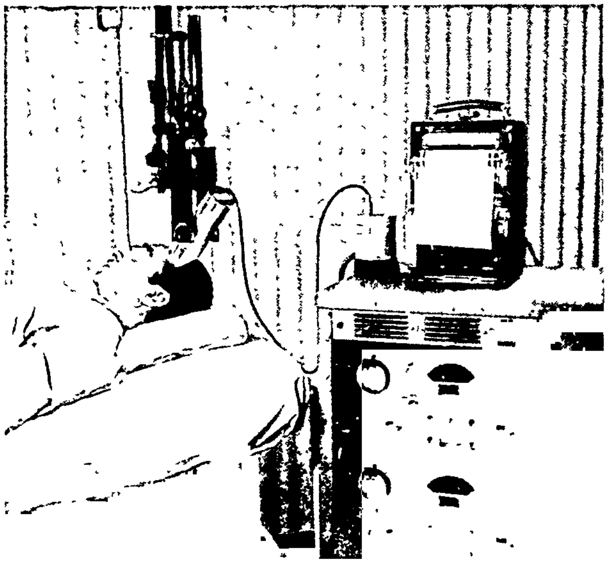

Fig. 1.—The shielded TGG 2 Geiger tube is connected through an amplifier to a General Radio Counting Rate Meter, and the counts per minute are recorded on an Esterline-Angus milliammeter. Note that the tube is maintained "normal" to the skull in this left superior precentral or frontal area (LF_3) position. Readings are at least of three minutes' duration over each site, and the most significant counting rates occur within ½ to 2 hours after the intravenous administration of 1.1 millicuries of radioactive diiodofluorescein.

1. A mica window Tracerlab TCG 2 Geiger-Mueller tube with a 250 mg/cm.^{2} aluminum cap which effectively eliminates most of the I^{131} beta radiations. The tube-sensitive diameter is 2.5 cm.

2. A lead shield with a thickness of 1.2 cm. This shield, in which the tube is mounted, extends 1.5 cm. beyond the end of the Geiger tube providing for a wide geometry. Maximum flexibility is achieved by attaching the shield and the tube to a 360 degree yoke and swivel, or similar device, which in turn is set on a wall-mounted dental x-ray tube arm.

3. A modified General Radio Counting Rate Meter, with a 1,000 count per minute full scale range, connected to the tube through a preamplifier.

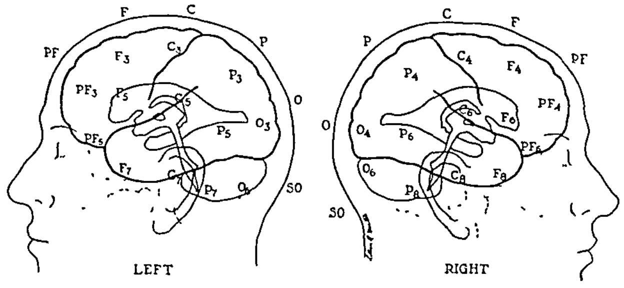

Fig 2—Note the 32 different positions surveyed with the Geiger tube, which covers every area of the skull on and above Reid's base line These include 13 positions on each side of the skull, 2 prefrontal (PF), 3 frontal (F), 3 central (C), 3 parietal (P) and 2 occipital (O), besides 6 midline positions. It is essential that at least all these areas be checked within the significant ½ to 2½ hour time interval following the radio fluorescein administration, because readings after three to four hours are only confirmatory.

4. A mechanical graphic recorder (the standard Esterline-Angus milliammeter) with a recording speed of 6 minutes per inch.

As seen from the pictorial chart (fig. 2), the survey covers at least 32 different positions on the scalp, including 13 areas symmetrically studied on each side of the skull, alternating from left to right, and 6 midline positions. In this fashion every inch of the skull on and above Reid's base line is surveyed with the counter. The Geiger-Mueller tube is placed directly on the scalp and is maintained "normal" to the skull, that is, at right angles to the tangent at the particular position under study. Readings are at least of three minutes' duration over each site and are repeated over abnormal areas at frequent intervals of time from 20 minutes to four hours after injection of the dye. The counts per minute are visually displayed and continuously recorded on the Esterline-Angus tracing, so that the abnormal concentrations can readily be diagrammatically transposed and recorded on the pictorial chart

Within a minute or two after the injection of the dye, the radioactivity at the surface of the head is at a maximum. This decreases rapidly over the next 10 to 30 minutes, until a plateau is observed. After this interval, and for the next 1 to 2 hours, the decline in counts is gradual, so that symmetric positions can be accurately studied, if care is taken in properly matching areas on each side of the skull within 3 to 5 minutes. The most significant counting rates occur within ½ to 2 hours after the administration of the radiodye; hence, suspected areas of involvement not only must be rechecked several times during this period, but also must be compared to the concentrations in adjacent areas, in order to delineate not only the main focus of the lesion but also its extent. The counting rates during this pertinent period, using the equipment described, is of the order of magnitude of 200 to 1,200 counts per minute

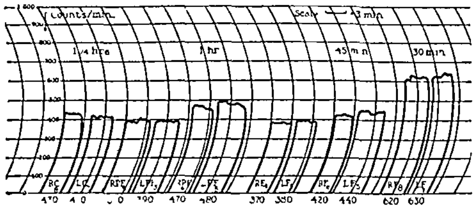

Fig 3—The normal radioactive diiodofluorescein concentrations in counts per minutes on an Esterline Angus tracing, at time intervals from 40 minutes to 1¾ hours after the intravenous administration of 1 1 millicuries of the dye Note that symmetric areas on each side of the skull are studied as simultaneously as possible within three to five minutes after a "plateau" is reached Note that in a normal patient the variations over symmetric sites are from 0 to 40 counts per minute and that those over adjacent areas have a characteristic normal variation as well Compare mid PF to mid F, mid C and mid P, or compare the left parasagittal frontal area to the left anterior temporal lobe (LF3 to LF7). Most of the non space occupying intracranial lesions fall within just such a range and include hypertensive cerebrovascular accidents, cerebral thrombosis, meningovascular syphilis, chronic arachnoiditis or ruptured cerebral aneurysm

It is essential to count at least all 32 sites, but, since there is only a limited significant time interval of about two hours, the order of the performance of the counting should vary so that the suspected areas are measured at least two to three times for greater accuracy. At the end of three to four hours the readings are only confirmatory, for the differential concentrations are no longer striking.

INTERPRETATION OF RESULTS

A range of normal concentrations has been determined for each position at various time intervals (figs. 3 and 4). If the observed concentration at all sites is greater than the upper range of normal by 100 to 600 counts per minute then a tumor should be suspected For localization of this tumor, comparisons are then made with the symmetric position on the opposite side of the skull and also with positions adjacent to the area under suspicion. In the normal subject, the counts made over symmetric sites vary from 0 to 40 counts per minute. Hence, 50 counts per minute is arbitrarily considered to be the lowest level of significance. The standard statistical error at rates of 500 and 1,000 counts per minute is 20 and 30 counts per minute, respectively. Therefore variations of more than 10 to 15 per cent are significant. It should be noted that the over-all increase of radioactivity in patients with verified brain tumors may be such that the count over the tumor itself may be 50 to 100 per cent greater than the count over the same site in a normal brain at a comparable time interval.

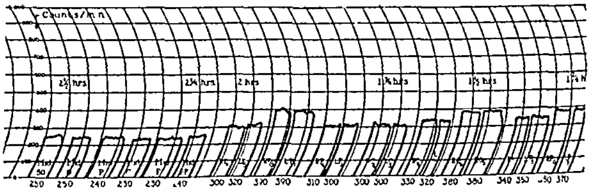

Fig 4—Continuation of the tracing shown in figure 3 at 1¼ to 2½ hours after the intravenous administration of 1.1 millicuries of the dye

From figures 3 and 4, which show normal values, it can be seen that adjacent sites have characteristic variations. The readings at the midparietal and midsuboccipital positions are 230 and 260 counts per minute, respectively, with a difference of 30. In a patient with a *verified tumor in the midsuboccipital area* (figs. 5 and 6), there were readings of 590 and 810, respectively, with a difference of 220, which is seven times the normal difference in these adjacent midline areas. Likewise, the concentration of the dye over the site of the suspected tumor was *810 counts per minute*, whereas the highest range of concentration in normal patients at the same site and for the same interval of time is only 250 counts per minute. The difference between these is 560, which is at least 10 times higher than our accepted difference of 50 counts per minute *in normal* persons. Differences of this magnitude are striking and are never seen in any but tumor patients.

Use of this method of comparison with the normal values, and with symmetric and adjacent area values for a pertinent time interval, has improved the reliability of our results and has made possible the diagnosis of midline and posterior fossa tumors.

RADIOLOGICAL HAZARD

Studies of the distribution and excretion of radioactive diiodofluorescein have been made in human beings, dogs and rats. The biologic half-life in man is two to three days. The highest concentration after the initial maximum occurs in the thyroid gland, and the dose of radiation delivered to this tissue is from 1.9 to 3.8 roentgen equivalents. This dose of radiation is substantially less than that received by patients tested with 50 microcurie doses of radioiodine in studies of thyroid function. The other tissues of the body retain considerably smaller amounts of the radiodye, and in none of the dogs was significant radioactivity detectable seven days after the administration of 25 microcuries per kilogram, or twice the usual dose in human subjects. We believe that there is no significant hazard to the patient from the use of diiodofluorescein in amounts of 1.0 to 2.0 millicuries.

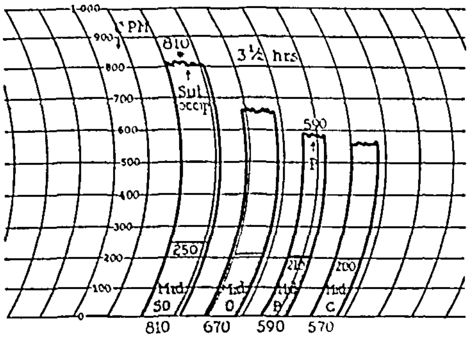

Fig 5.—Patient D C clinically showed signs and symptoms of a right parietal lobe neoplasm Ventriculography was equivocal, demonstrating only mildly enlarged lateral ventricles The radioactive fluorescein study revealed a high tumor concentration especially in the posterior fossa and upper part of the cervical cord At surgical intervention, a vascular mixed cell astrocytoma was partially removed from this site Note that 3½ hours after administration of the radiodye the concentration in the middle posterior fossa or midsuboccipital (SO) area is 810 counts per minute, which is 220 counts per minute more than the adjacent mid parietal area (P = 590), a difference seven times the expected normal variation of 30 counts per minute at this period of time Also note that the total concentration of 810 is 560 above the highest normal value of 250 (see shaded area) ever noted for the midsuboccipital area at 3½ hours These readings are highly significant of a vascular and cellular tumor.

CLINICAL EXPERIENCES

There were 95 histologically verified space-occupying lesions of the central nervous system; 40 of these were gliomas, 13 were meningiomas and 13 were metastatic carcinomas and sarcomas. The remaining 29 included 6 tumors of the spinal cord, 7 tumors of the hypophysis, 2 hemangioblastomas of the cerebellum, 1 acoustic neurinoma, 1 melanoblastoma, 3 unclassified intracranial tumors, 4 subdural hematomas, 2 cerebral abscesses, 1 porencephalic cyst, 1 arteriovenous fistula and 1 granulomatous cyst. In these 95 patients, 86 (91 per cent) lesions were accurately diagnosed as organic and localized with radioactive fluorescein, while only 4 diagnoses were completely inaccurate. The other 5 were inaccurate only so far as the nature of the lesion was concerned but were accurate in respect to localization of the lesion. Thirty-eight of the 40 gliomas studied were accurately diagnosed, and these included 20 glioblastomas, 16 astrocytomas, 3 oligodendrogliomas and 1 ependymoma. The 2 gliomas diagnosed inaccurately were in the cerebellum, and each was composed of a large, single cyst. By radioactive assays we have shown that the liquid contents of such cysts contain even less radiodye than the normal brain.

Besides these 95 microscopically verified space-occupying lesions, there were 15 grossly verified presumptive gliomas which were surgically treated and proved to be inoperable and are, at this time, microscopically unverified. All these lesions were accurately diagnosed and localized with the radiodye test. These included lesions of 10 patients with brain stem tumors, 5 of whom had ventriculocysternostomy performed and 5 deeply-seated temporal lobe tumors close to the midline.

Of the total of 110 microscopically and grossly verified space-occupying lesions, 101 (92 per cent) were accurately diagnosed and localized by means of the radioactive isotope tracer test. This exceeds by far the accuracy of all other neurosurgical tests or procedures, particularly with regard to localization. Added to this group of 101 are 18 patients with presumptive space-occupying lesions in whom this method corroborated the clinical and roentgenologic diagnoses Lesions of these patients await surgical verification and/or further observation. The remaining 72 of the 200 tumor-suspect patients were thought not to have a space-occupying lesion by this test, and this diagnosis was supported by surgical exposure in 13 instances, air studies in 54 instances and/or angiography in 5 instances. Of these, only 1 yielded a positive dye concentration in the absence of tumor

Clinically, this patient had the typical signs and symptoms of a cerebellar pontine angle tumor. The radiodye test also localized the tumor in this region However, suboccipital craniectomy revealed no tumor but only a mass of dilated blood vessels and fibrous tissue, which was considered to represent a chronic infectious process. These pathological changes were the cause of the clinical signs and symptoms, and the abnormal blood vessels were probably responsible for the slight but persistent uptake of radioactive fluorescein

In all 200 cases there were only nine proved inaccuracies, making a total accuracy of 95.5 per cent for the radioactive diiodofluorescein test. Eight of the nine were intracranial lesions, and all but one were also inaccurately diagnosed by clinical examination, electroencephalography and pneumography. The first patient has been discussed in the preceding paragraph.

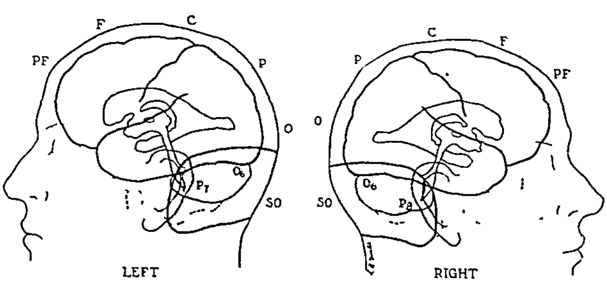

Fig 6.—Pictorial chart used for recording the graphic record seen in figure 5, in which the abnormal concentrations are diagrammatically transposed and recorded

The second of these patients had clinical signs pointing to a left frontal lobe tumor extending in butterfly fashion across the corpus callosum The radiodye concentration was slight but persistent in the right temporal lobe. The patient was scheduled for a large left frontotemporal craniotomy, but before surgical intervention could be performed the patient expired suddenly during a bout of coughing. Autopsy revealed an astrocytomatous cerebellar cyst without a mural nodule and with no evidence of any lesion in either cerebral hemisphere

The third patient had clinical, roentgenologic and radiodye evidence of a lesion in the right hemisphere consistent with a diagnosis of subdural hematoma. At surgical intervention an encapsulated hemorrhagic mass was removed at the site indicated by the radiodye test. Microscopic examination revealed a metastatic hypernephroma with extensive cyst and hematoma formation, which no doubt accounted for the diminished concentration of radiodye. Later, a fluorescein restudy revealed an extensive lesion, typical of metastatic carcinoma, whose plotted extent coincided accurately with the actual size and extent of the tumor in the right temporal lobe, as proved at autopsy.

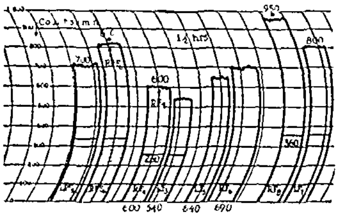

Fig 7

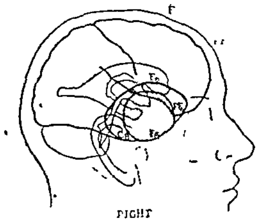

Fig 8

Fig 7—A portion of the actual tracing 1½ hours after the intravenous injection of 1 1 millicuries of radiodye The significant value, 950 counts per minute is marked by an asterisk and was obtained over position RF_8 (right middle cranial fossa, on Reid's base line) The highest value found in a normal patient in this position at this particular interval of time is shown by the shaded portion, i e, 360 counts per minute *Over the symmetric site on the opposite side of the skull* (LF_7) there were 800 counts per minute The right posterior inferior frontal area (RPF_6) registered 820 counts per minute as against only 700 over the same symmetric area on the opposite side (LPF) Also note that the adjacent sites RF_8 (950 counts per minute) and RF_4 (600 counts per minute) at the base and vertex respectively, of the right middle cranial fossa, show a wide difference of 350 as compared to a normal difference of 100 over the same sites in a normal patient The tracing therefore indicates a lesion, deep in the middle fossa, which is relatively highly vascular and cellular.

Fig 8—Pictorial chart of the graphic record in figure 7, showing the *lesion at the base of the middle fossa on the right* (RF_8), extending interoinferiorly to area RPF_6.

The fourth patient appeared to have, clinically, roentgenologically and by radiodye studies, a lesion in the right parietotemporal area. However, when surgical operation was performed a small, well encapsulated subdural hematoma was discovered, exactly occupying the site designated. On microscopic examination, the capsule was found to be exceedingly thick and to contain a great many newly formed capillaries The latter probably accounted for the relative increase of radiodye in this area.

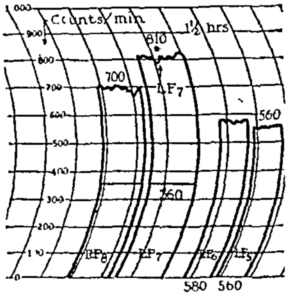

Fig 9

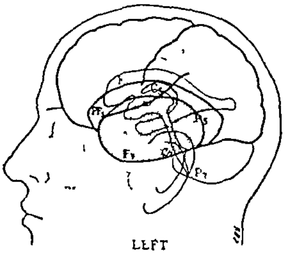

Fig 10

Fig 9.—A portion of the graphic tracing at the site of an extensive glioblastoma multiforme in the left temporal lobe, proved both at surgery and later at autopsy to be accurate in its focal localization The radiodye concentration at LF_7 is 810 counts per minute 1½ hours after administration, as *compared to 700 at* RF_8, the same basilar position on the opposite side, a difference of 110 counts per minute The shaded portion again represents the highest range of normal for this position (360 counts per minute) The difference of 450 counts per minute is striking, and is highly significant of tumor Note that the adjacent positions LF_6 (580) and RF_6 (560) show 200 counts per minute less than the tumor area LF_7 (810) and differ only 20 counts per minute from one another.

Fig. 10—Pictorial representation of the graphic tracing seen in figure 9, showing the actual extent of the large tumor in the left temporal lobe, which was verified surgically and at autopsy as a glioblastoma multiforme

The fifth patient had generalized Hodgkin's disease with vague clinical involvement of the spinal cord and with a myelographic block at the seventh dorsal vertebra Laminectomy revealed an extensive extradural tumor at that level The radiofluorescein concentration appeared to be more intense in the lumbar and sacral areas, and this corresponded to the involvement of mesenteric and paraaortic nodes, which had recently been treated with high voltage roentgen radiation The diagnosis of tumor was correct, therefore, but the localization was accurate only for the abdominal area of the spine and not for the thoracic spinal involvement.

The sixth patient was struck on the head a week previous to examination but had no period of unconsciousness His only complaint was headache. He had no other symptoms or signs except a questionable right facial weakness. Pneumoencephalography revealed *an equivocal shift of the ventricles to the left* The radiodye concentrations were persistently high in the middle *cranial fossa, slightly greater on the right than on the left,* and were consistent with a diagnosis of tumor in the temporal lobe area Surgical intervention revealed bilateral subdural hematomas in the middle fossa. Hence, it is possible that in this case of recent trauma, with its associated disturbance in cerebral capillaries, there was an increased exudation of radioactive fluorescein, accounting for the high counts seen in this patient As we learned later, repeated studies in recent post-traumatic cerebral lesions reveal a decreased dye concentration within seven to 10 days, in contrast to neoplastic lesions, which show the same or an increased concentration. We believe that, in future patients in whom trauma is an etiological factor, we will be able to avoid such errors by repeating the radiodye test.

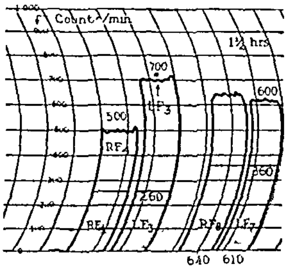

Fig 11

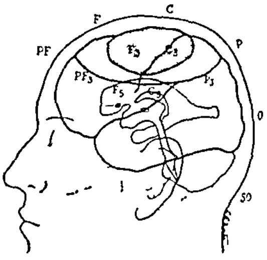

Fig 12

Fig 11—The site of the highest radiodye concentration is the LF_3, or left parasagittal precentral area, where the counts per minute are 700 as *compared to 500 on the right side,* RF_4 *Normally, a difference* of only 40 counts per minute exists The adjacent basilar site is usually 100 counts per minute higher at this period of time (1½ hours): however, in this instance the parasagittal vertex reading is 90 counts higher than LF_7 (610), showing a complete reversal from the normal dye concentrations

Fig. 12.—Pictorial chart corresponding to figure 11. This space occupying lesion was accurately outlined by the radiodye concentrations and proved at surgery to be a meningioma The shaded area represented that portion of the tumor which was superficial The remainder of the outlined area was occupied by the meningioma which was present beneath the cortex

The seventh patient, a man aged 41, had had a pneumonectomy performed three weeks previously for the removal of a verified bronchogenic carcinoma. His only complaint was two generalized seizures four days before admission. The neurological examination revealed completely normal conditions as did the spinal fluid studies. The radiodye concentrations were at the upper limits of normal without pertinent localizing signs However, pneumography showed a definite shift of the left lateral ventricle to the right with a large defect in the left posterior temporal lobe. Craniotomy revealed a well encapsulated, firm tumor nodule which was the size of a walnut. Several weeks later autopsy revealed that the entire left temporal lobe was occupied by a decidedly necrotic, centrally cystic, metastatic carcinoma. Even the thin peripheral rim of tumor tissue showed evidence of severe liquefaction necrosis. This tends to corroborate further that it is only the actively growing tumor which concentrates the radiodye, since the cystic portions actually have a diminished uptake.

The last two of these nine patients demonstrated this feature most completely. Both had cystic tumors of the posterior fossa: one was a tremendous cyst with a small astrocytomatous mural nodule, and the other was a nonspecific granulomatous cyst with a thickened, white, avascular capsule. In both of these instances the radiodye concentrations were even lower than those for the adjacent normal brain tissue. When the preponderance of cyst fluid over tumor cells and tumor capillaries is too great, the radiodye concentrations are not significantly increased even though a small tumor nodule may coexist with the large cyst. However, in the greater number of instances, even in the multicystic, relatively avascular astrocytomas, there is usually a sufficient number of neoplastic cells and capillaries to result in a recordable, pertinent, differentiating radiodye concentration. In only one instance did a simple cyst reveal its presence by a slight focal concentration of radiodye. This was in a patient with a traumatic porencephalic cyst in which the differential concentration was quite definite but at the lowest level of significance. Added to this was the fact that the record was taken 5 days after pneumoencephalography was performed; the latter in itself will cause a slight generalized increase in radiodye concentration, probably the result of the irritative effect of residual intraventricular oxygen on the adjacent cerebral capillaries.

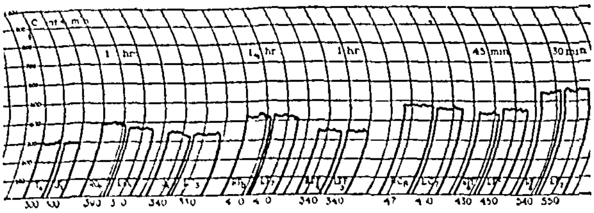

Fig 13.—Normal tracing obtained in L. J., a patient aged 25 with clinical symptoms and signs of a neoplasm in the right frontal lobe. The radiodye concentration counts were within normal limits from ½ to 2½ hours after injection of the dye. This tracing made in the ½ to 1¼ hour interval did not support the diagnosis of a space occupying lesion in the right frontal lobe.

RELATIONSHIP OF THE RADIODYE CONCENTRATION TO THE HISTOPATHOLOGY OF CENTRAL NERVOUS SYSTEM TUMORS

There appeared to be a definite gradation of differential counts per minute over symmetric areas of the skull, as also when contrasted with the normal values at the same interval of time, and this was related not only to the degree of malignancy of the tumor but even more so to its angioarchitectural pattern and its degree of anaplasia. Metastatic carcinomas and sarcomas (figs. 7 and 8) gave counts in the highest differential range. Next were the glioblastomas (figs. 9 and 10), in which the concentration of radiodye appeared to be definitely related to the degree of endothelial or adventitial proliferation of the capillaries and to the disturbed permeability of their endothelial cells. For example, the angioproliferative glioblastomas[16] showed a lower range of counts per minute difference between symmetric areas of the skull than did the angiothrombotic types. Next in the differential range were the vascular and cellular meningiomas (figs. 11 and 12), with the more fibrous hyalinized types giving lesser degrees of radiodye concentration. The patients with astrocytoma and oligodendroglioma showed the lowest differential count of all the tumors. This appeared to coincide directly with the relative microscopic scarcity of capillaries in these tumors. However, recurrent gliomas had a much greater uptake of dye, and this was consistent with their increased cellularity and vascularity.

At the base of the scale of radiodye concentration were the chronic subdural hematomas and the extensively cystic tumors. It was noted that in the acute stage of a hemorrhage the concentration over the focal site never reached the heights seen in tumors; if the radiodye test was repeated within two to three weeks, the concentrations were as normal as in the chronic hematomas. Undoubtedly, the cerebral edema and disturbed vascularity in the acute stage accounted for the temporary increase of radiodye. In tumor patients, on the contrary, repeat studies revealed an increase instead of a decrease in dye concentration.

Three instances of subarachnoid hemorrhage secondary to a ruptured intracranial aneurysm showed normal readings. Because of the presence of papilledema these patients were clinically considered to be tumor suspects. One of these (figs. 13 and 14) even had a craniotomy performed because electroencephalography, ventriculography and angiography all pointed to a space-occupying lesion in the right frontal lobe. However, operation revealed an aneurysm of the anterior cerebral artery, visualized on the floor of the anterior cranial fossa, as well as multiple areas of old intracerebral hemorrhagic softening. Biopsy specimens of normal and neoplastic brain tissue are being assayed in our radioisotope laboratory. Preliminary results tend to confirm our impressions obtained by external counting; namely, cysts contain less dye than normal brain, while tumors contain more dye, dependent on their degree of cellularity and vascularity.

RELATIONSHIP TO PREOPERATIVE DIAGNOSIS

Clinically, a focal diagnosis of lobe involvement was made in 54 of the patients and a more diffuse localization was made of hemispheric involvement in another 14. Previous to confirmation by air studies, there were 64 patients in whom the preoperative clinical impressions were inaccurate. In many of these the radiodye test proved of particular value, especially in patients with papilledema, where the differential diagnosis between intracranial neoplasm, hypertension, arachnoiditis and intracranial aneurysm was especially difficult despite the aid of electroencephalography, pneumography and angiography. The radioisotope tracer studies confirmed the localization and diagnosis made clinically in all but 5 per cent of patients. In 7 of the 9 patients whose condition was inaccurately diagnosed by radiodye studies, the clinical signs and symptoms were also inaccurate. At times difficulty was encountered in differentiating a

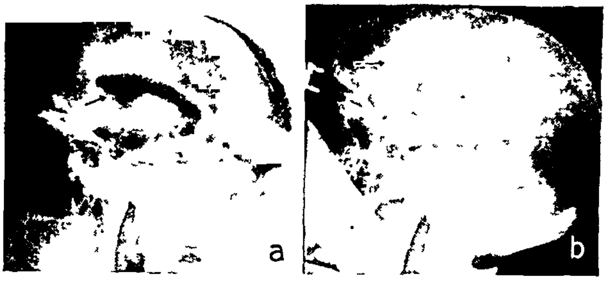

Fig 14.—Ventriculogram (left) and angiogram (right) of patient L. J., whose tracing is shown in figure 13, reveal a space occupying lesion in the right frontal lobe.

[16] Davis, L., Martin, J., Goldstein, S. L., and Ashkenazy, M.: A Study of 211 Patients with Verified Glioblastoma Multiforme, J. Neurosurg. 6: 33-44, 1949.

posterior fossa tumor from one in the frontal lobe. In two such instances, in which the clinical diagnosis of right frontal lobe neoplasm and of right parietal lobe neoplasm was made, radioactive fluorescein studies revealed high concentrations in the right cerebellar and in the midsuboccipital areas. Ventriculography revealed only a moderate hydrocephalus in each case. At surgical intervention a cystic hemangioblastoma and a mixed cell astrocytoma were removed from the sites postulated by the positive radiodye test.

RELATIONSHIP TO ELECTROENCEPHALOGRAPHY

Electroencephalographic studies were performed in 110 of the 200 patients; a slow wave focus diagnostic of tumor was made in 30, while a more diffusely localizing diagnosis was made in 8. There were 26 patients with intracranial tumors and 10 without tumors who had normal or falsely localizing electroencephalograms. Lesions of these patients included 5 glioblastomas, 4 meningiomas and 2 astrocytomas in the cerebral hemispheres, 5 brain stem tumors, 4 pituitary tumors and 2 hemangioblastomas, 2 metastatic carcinomas and 2 astrocytomas in the posterior fossa. In all 36 cases of electroencephalographic inaccuracies the radiodye studies were accurate. For the most part, even the focal diagnosis made by electroencephalography was never as precisely localizing as either the pneumographic or radiodye studies. Frequently there was a wide spread of the response from the involved lobe. Even when localization by electroencephalography was positive, it was sometimes difficult to determine whether the slow wave focus was due to a neoplasm, cerebral hemorrhage, subdural hematoma or contusion of the brain.

RELATIONSHIP TO PNEUMOENCEPHALOGRAPHY AND VENTRICULOGRAPHY

Air studies were performed in 121 of the patients. In 30 of these a focal lesion was localized; in another 27 a more diffuse lesion was localized. The remaining 46 patients had normal air study films. There were 18 inaccuracies. In 10 of these the clinical observations and encephalograms were sufficiently suggestive of tumor that it required 8 craniotomies and 3 suboccipital craniectomies to rule out such a lesion. In all but one instance the radiodye test proved correct. Of the 8 patients who had negative air studies in the presence of a verified tumor, all but one of these had their lesions accurately diagnosed by the radiodye test as tumors.

We believe that radioactive dye studies, by their more precise localization as to lobes, have proved of great value to the neurosurgeon, especially in that group of 27 patients in whom air studies revealed only a diffuse hemispheric involvement. In many cases, filling of the ventricles is difficult or incomplete owing either to technical difficulties or to anomalous or blocked foramens of Magendie or Luschka. In ventriculography poor filling may result from the massiveness of the space-occupying lesion or the severe surrounding edema, features commonly found in glioblastomas or metastatic tumors. Pneumoencephalography, with its severe headaches and occasional shock, as a whole is an exceedingly discomforting procedure as far as the patient is concerned. This is in contrast to the relative harmlessness and simplicity of the radiodye test. As is also well known, ventriculography in itself, though accurate, is not altogether a harmless procedure, and a certain percentage of deaths from this cause alone are recorded in all neurosurgical clinics.

RELATIONSHIP TO OPERABILITY

Surgical operations were performed on 124 patients, and space-occupying lesions were found in 110 instances, 95 of which were microscopically verified. There were 10 patients in whom a tumor was not found at operation, and in only one of these did the radiodye test show tumor localization. In a man aged 57 with a history of recent onset of headaches, dizziness, tinnitus and poor vision, and with evidence of an enlarged sella turcica, ventriculography revealed a hydrocephalus, and a diagnosis of posterior fossa neoplasm was made, despite a negative radiofluorescein test. A suboccipital craniectomy revealed no evidence of tumor. A ventriculocysternostomy was performed because a midline tumor was still postulated. Later, the patient had further visual field changes and a left central facial paresis. It was then believed that he had a pituitary neoplasm, despite the normal radiodye test. A right transfrontal craniotomy was then performed, and again no tumor was found; only evidence of perichiasmal arachnoiditis was seen. The absence of a tumor was verified later at autopsy. In this one patient two major surgical procedures were performed because of the strong clinical and pneumographic evidence of tumor, although none existed as demonstrated by the normal radiodye concentrations.

On the basis of multiple foci of radiodye concentration we have been able to predict accurately the presence of metastatic lesions in 50 per cent of the cases in our series of metastatic carcinomas and sarcomas. In one patient both a left temporal and a right postcentral tumor focus were noted with the radiodye test, although clinically he presented signs only of an obvious left cerebral expanding lesion. One month after the removal of a left temporal anaplastic carcinoma, there developed a left hemiparesis, which was even more pronounced than that on the right, thus clinically supporting the preoperative radiodye evidence of another focus in the opposite hemisphere. Postoperative studies were performed in about 60 per cent of the tumor patients, and thereby we have been able to prognosticate the extent of recurrences of intracranial tumors. These have correlated well with either the progressive or regressive clinical signs and symptoms as well as with the various types of surgical attack and the degree of completeness of removal of such tumors at operation. In four patients with a meningioma, an oligodendroglioma, a hemangioblastoma and a glioblastoma multiforme the tumor was well demarcated at surgical intervention and could be removed completely. In these cases our postoperative studies revealed no tumor concentration, although preoperative studies showed a positive concentration typical of that particular type of tumor.

In the cases of partial excisions of the tumor postoperative studies revealed evidence of tumor concentration, and in practically all these instances the uptake was more intense and appeared earlier than in the preoperative studies. This may be significant of increasing malignancy of the lesion after surgical intervention, a fact fairly well substantiated clinically and histopathologically, especially in those patients with glioblastoma multiforme who appear to go downhill rapidly after a surgical operation. On the other hand, the associated decompression performed by the removal of the bone flap tends to cause the tumor to gravitate toward the surface, which is now the area of least resistance. In this instance, the inverse square law of electricity comes into effect and may be the cause of the increase of the differential count, merely as the result of the more superficial position of the tumor. This was found to be especially true in those patients who had deep-seated lesions situated near the midline at the time of surgical intervention. However, that the absence of the bone in itself is not the underlying cause of the increased count is shown by the fact that there was no significant difference in counts recorded in the three patients of the four with completely resectable tumors mentioned above, when the overlying bone was removed for decompression purposes.

RELATIONSHIP TO HIGH VOLTAGE IRRADIATION

High voltage roentgen therapy does not seem to have any effect on the absorption of radioactive fluorescein by normal brain tissue or by the more benign gliomas. One patient had a grossly encapsulated oligodendroglioma removed almost completely. Postoperative studies four weeks later revealed only 60 counts per minute differential at the tumor site. This was about one third of the difference noted on his preoperative study and was significant of a slight residuum of tumor tissue which was probably deeply located. The radiodye test performed two weeks after high voltage irradiation again showed no increased uptake of dye. However, the exact opposite was noted in the more infiltrating and vascular tumors. For example, in six patients with glioblastoma multiforme and one with metastatic carcinoma, studied after radiation therapy, the uptake was decidedly increased and was persistent at frequent time intervals; also, it appeared much earlier after the intravenous administration of the dye than it had preoperatively. As noted by Davis and Weil,[17] high voltage roentgen therapy in some glioblastomas may cause striking histopathological changes in the parenchymal cells as well as in the stroma and blood vessels. This tends to increase the already altered permeability of these smaller capillaries and leads to an increased exudation of radiofluorescein dye. To the effect of high voltage roentgen therapy must be added the concurrent effect of removal of the bone flap, which is usually complete in glioblastomas and metastatic tumors.

RELATIONSHIP TO TUMOR SITE

Accuracy was consistent in the superficially located tumors, especially the meningiomas, with the differential count being both high and persistent. This was true not only in the cerebral hemispheres but also in the posterior fossa in such tumors as hemangioblastomas, astrocytomas and metastatic carcinomas. If the tumor proved to be a glioblastoma or a metastatic carcinoma or sarcoma, the site seemed to make little difference; the dye concentration was always sufficiently intense to make diagnosis certain. However, in the case of tumors close to the midline in the region of the hippocampal gyrus, or in the region of the pituitary, hypothalamus or upper part of the brain stem the differential counts were much lower, because of the action of the inverse square law of electricity as the distance from the skull to the tumor increased. Of added aid in such cases was the high differential count in homolateral readings from the parasagittal areas to the base, in the middle fossa in particular, since the symmetric skull readings were equal.

The clinically silent areas of the brain such as the anteromedial aspect of the temporal lobe or posterior-inferior frontal lobe have been relatively easy to diagnose with the aid of this radioactive diiodofluorescein test, even when the electroencephalographic and pneumographic studies were equivocal. A woman aged 58 had generalized seizures of one year's duration, with minimal nonlocalizing signs. Results of electroencephalography were normal, while pneumoencephalography showed only widened subarachnoid spaces indicative of cerebral atrophy. The radiodye studies revealed a persistent concentration typical of a tumor in the right temporal lobe. Craniotomy revealed no evidence of increased intracranial pressure; in fact, there was atrophy of the temporal lobe with softening. A gross diagnosis of cerebral softening was made, until the microscopic sections revealed a fibrillary astrocytoma.

RELATIONSHIP TO SPINAL CORD TUMORS

Eleven patients suspected of having a spinal cord neoplasm were studied. Six of these had verified tumors, two of which were ependymomas, one chordoma, one lymphosarcoma, one lymphoblastoma and one metastatic carcinoma. The radiofluorescein test was accurate in five of these but in the other one only partially so. The other five patients revealed no concentration of radiodye typical of tumor, and the absence of a space-occupying lesion was proved by laminectomy. Within the spinal cord the problems of diagnosis and localization are much more difficult, because gamma radiations are also being recorded from the adjacent liver, spleen, lungs and intestines. Hence, for greater accuracy it is important to have as a control a patient of almost equal weight and stature. This problem is being further pursued, and it appears likely that at the present stage of instrumentation, only tumors far removed from the chest and abdomen, that is, in the cervical and lower lumbosacral regions of the spine, will be accurately localized with the radiofluorescein test.

SUMMARY

In 200 patients suspected of having central nervous system tumors, studied by means of radioactive diiodofluorescein, the results reveal a 95.5 per cent accuracy in diagnosis in lesions verified by surgical intervention or corroborated by pneumography or angiography. The technic is simple, and instrumentation consists of a Geiger-Mueller tube, a counting rate meter and mechanical graphic recorder. There was a 91 per cent accuracy in the 95 histologically verified space-occupying lesions of the central nervous system, which included 40 gliomas, 13 meningiomas, 13 metastatic carcinomas and sarcomas, 7 pituitary tumors, 6 spinal cord tumors, 2 cerebellar hemangioblastomas, 1 acoustic neurinoma, 1 melanoblastoma, 3 unclassified tumors, 4 subdural hematomas, 1 porencephalic cyst, 2 cerebral abscesses, 1 arteriovenous fistula and 1 granulomatous cyst. A positive radiodye test was recorded in five of the six verified tumors of the spinal cord.

---

[17] Davis, L., and Weil, A.: The Effect of Radiation Therapy upon Intracranial Gliomata, Ann. Surg. **106**: 544-616, 1937.

The affinity of radioactive dye for tumor tissue was related to the cellularity and vascular pattern of the tumor. The more malignant the neoplasm, the greater was the radiofluorescein concentration. Metastatic carcinomas and sarcomas gave counts of the highest differential range. Next were the glioblastomas and the vascular cellular meningiomas. The astrocytomas and oligodendrogliomas showed the lowest differential count of all the tumors, coinciding directly with the relative microscopic scarcity of capillaries in these tumors.

There was little or no concentration of dye over the site of chronic subdural hematomas, because these are relatively avascular lesions. The radiodye concentrations over large cysts are even lower than over adjacent normal brain tissue. In a cystic degenerative tumor only the actively growing tumor tissue concentrates the radiodye, whereas the cystic portions actually have a diminished uptake. In areas where the preponderance of cyst fluid over tumor cells and tumor capillaries was too great, the radiodye concentrations were not significantly increased and gave rise to most of the errors encountered with this method.

The negative results also proved to be 95 per cent accurate and were of equal importance in the differential diagnosis of cerebral neoplasms, especially from such lesions as hypertensive cerebrovascular accidents, perichiasmal arachnoiditis, meningovascular syphilis and intracranial aneurysms.

Localization by the radiodye method proved to be much more precise than with electroencephalography or pneumography, whenever verification was obtained at surgery or at autopsy. Pneumography was 63 per cent focally accurate, and electroencephalography was only 45 per cent focally accurate. Tumor recurrences could be demonstrated readily with this technic. Postoperative high voltage roentgen therapy caused an increased concentration of radioactive diiodofluorescein in the more malignant intracerebral neoplasms. Special technics of counting have been evolved, so that the accuracy of localizing midline tumors, such as those of the pituitary, brain stem or posterior fossa, is as accurate as that of localizing the more superficially situated cerebral neoplasms.

With the apparatus and technic described above, the limitations of the test have proved to be few, provided due regard is had to accurate consistent placement of the Geiger tube on the skull and provided suspicious areas are rechecked and compared to symmetric and adjacent areas of the skull. Space-occupying lesions in every area of the skull have been localized accurately. Occasionally, localization was more diffuse, and even lateralization was difficult; in all these cases the tumor was at or near the midline or had actually crossed the midline; in several instances lesions which showed no localizing symptoms on clinical examination of the patient and in which pneumography was of no aid were accurately localized with the radiodye test, as proved at operation or autopsy.

We believe that the radioactive diiodofluorescein tracer test is a simple, safe, painless and reliable method for the localization and diagnosis of brain tumors, and one which should grow in value as increasingly more sensitive detection equipment and more specific radiodyes become available.

RELIEF OF ANGINA PECTORIS BY SYMPATHECTOMY

Report of Results in Ten Patients Subjected to High Thoracolumbar Sympathectomy Including the Anginal Pathway

JAMES A. EVANS, M.D.
JAMES L. POPPEN, M.D.
and
JAMES B. TOBIAS, M.D.
Boston

In April 1948 Evans and Bartels,[1] in reviewing the results of high thoracolumbar sympathectomy for essential hypertension, expressed dissatisfaction with the fact that anginal pain had been relieved in only 11 (73 per cent) of 15 patients subjected to the usual resection (fourth thoracic to second lumbar ganglions) of Poppen. For patients with severe angina we resolved in the future to remove a greater part of the anginal pathway which had been demonstrated by White, Garrey and Atkins[2] in the dog to include the first four thoracic sympathetic ganglions. Removal of these ganglions had been performed by Lindgren and Olivecrona[3] in 71 patients with angina pectoris, not all of whom had hypertension, with complete relief of pain in 44 per cent and partial relief in 41 per cent. White and Bland[4] reported that their results in 8 patients, 2 of whom had hypertension, showed that "resection limited to the upper three thoracic ganglions is nearly certain to afford complete relief of pain on the side of operation." Klemme[5] believed that his experimental work in dogs showed that the first thoracic ganglion could be spared and relief of anginal pain and coronary vasospasm achieved by removal of only the second through the fifth ganglions on the affected side. He reported one case in which this had been true.

Our own experience that a large percentage of hypertensive patients obtain relief of anginal pain without having resection of even a part of the so-called anginal pathway has been borne out by others. Peet,[6] reporting operations to the eighth thoracic ganglion as the upper level, stated: "Angina pectoris, either in a mild or severe form, occurs commonly in hypertensive patients. It may be the result of simple coronary spasm but in many it is probably due to actual arteriosclerosis of the coronary vessels. Particularly . . . when the hypertension is of long duration . . . the patient with anginal attacks has certainly a much graver prognosis. Fortunately many patients with angina pectoris have complete relief following splanchnicectomy."

Peet reported two cases of angina; one patient obtained relief for 10 years, the other had coronary occlusion before operation but no pain for five years after surgical intervention. The same author again wrote[7] that resection to the seventh or eighth thoracic

ganglion gave striking relief of anginal pain and palpitation. Some patients were completely relieved. In a few instances the electrocardiogram again became normal.

Peet[8] affirmed his belief that resections of the sympathetic chain to an upper level of the eighth thoracic ganglion together with splanchnicectomy help angina by relieving strain. He entirely relieved 14 patients of angina for five years. Of 68 patients with hypertension who had angina, 42 (62 per cent) survived five to 12 years, and half of these, or 31 per cent, obtained definite relief; 14 patients had complete relief of angina for five years or more. None of Peet's operations involved the anginal pathway.

During the course of several years, Grimson[9] performed so-called total sympathectomies on 133 hypertensive patients. This operation includes the anginal pathway. All but two of 33 patients with precordial pain in this group of 133 hypertensive patients were relieved. He stated: "Since the operation interrupts both nervous pathways conducting pain from the heart and sympathetic cardiac accelerators, elimination of these complaints is expected in all cases. The exceptional persistence in the few might be explained by error in subjective observations."

Smithwick[10] corroborated Grimson's observation in a group of 15 hypertensive patients with angina on whom he performed thoracic sympathectomy and splanchnicectomy to the level of the first thoracic ganglion.

OBSERVATIONS ON THE ANGINAL PATHWAY

The so-called anginal pathway is well accepted as passing through the inferior cervical ganglion (first thoracic) and those ganglions below it, including the fourth thoracic (fig. 1). The early resections of the cervical ganglions as pioneered by Jonnesco[11] proved failures because, as now known, direct fibers pass from the cardiac plexus to the second and third thoracic ganglions. According to White and Bland[1] the afferent pain fibers stimulated by cardiac anoxia and running in the middle and inferior cardiac nerves are all concentrated through the inferior cervical ganglion or stellate ganglion and the first thoracic ganglion usually fused with the stellate. There are also direct connections from the cardiac plexus passing through the second and third thoracic and probably the fourth thoracic ganglions.

It is not certain, according to White, whether pain fibers from the heart pass through the fourth thoracic ganglion. We are inclined to believe that they do because by extension of the resection level in splanchnicectomies for hypertension with angina pectoris from a point below the fourth thoracic ganglion invariably to include this ganglion the relief of anginal pain was raised from 12.5 to 73 per cent. This notable increase in satisfactory results cannot be the result solely of relief of the cardiac load from drop in blood pressure or of prolonged rest after operation. White and Bland[1] noted one case in which it was necessary to resect the fourth thoracic sympathetic ganglion on the left before a good result was obtained. In contrast, one of our patients who was subject to anginal attacks from whom the second and third thoracic ganglions were removed bilaterally for Raynaud's disease and scleroderma continued to have attacks of pain in the left arm although the substernal component was completely relieved. Removal of the fourth thoracic ganglion in this patient was not necessary, therefore, to abolish substernal pain. It would appear that the persistent pain in the left arm in this patient is mediated through the first left thoracic ganglion. This case is not included in the reported series because the patient did not have hypertension and the operation was not purposely designed to relieve the angina, the fear being entertained at that date of robbing her of warning anginal pain. Two similar cases are included in the series; in these the left arm pain persisted when the first thoracic ganglion on the left was not resected. However, left arm pain did disappear in three patients whose first thoracic ganglions were left untouched.

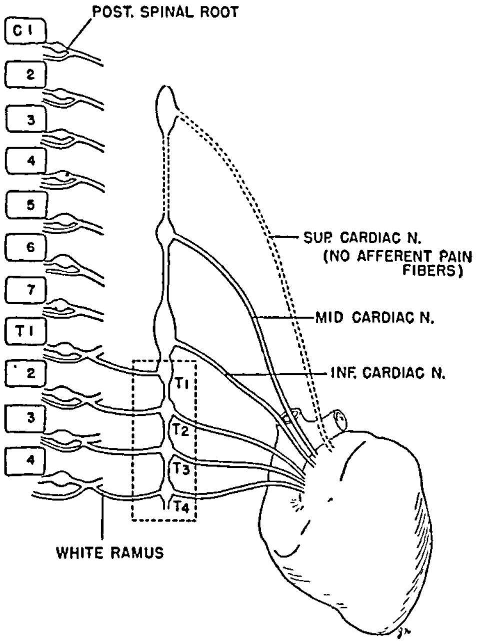

Fig. 1.—The cardiac afferent pain pathway. Note how the anginal pathway is funneled through the first, second, third and fourth thoracic ganglions.

Complete relief of anginal pain was obtained in five patients, four of whom had the first thoracic ganglion on the left resected. In two of these patients not even throat pain occurred after operation. The weight of evidence therefore seems to indicate the importance of including the first thoracic ganglion in order that the patient may obtain complete relief. The recurrence of pain on the right in two patients leads us now to advise bilateral resection to the first thoracic sympathetic ganglion. This decision is consistent with the well recognized anatomic facts as demonstrated by White and Bland[4] and previously in animal experiments by White, Garrey and Atkins.[2]

As we embarked gradually on these procedures, our hesitancy to carry resection immediately up to the stellate ganglion was caused by the desire to avoid ptosis. In some cases it is difficult to avoid resection of part of the stellate ganglion and the production of a Horner's syndrome if fusion of the first thoracic with the stellate ganglion is too close. None of our patients complained who did obtain a ptosis, however, and it has been our observation that in time the ptosis becomes less decided. The fact that the higher the resection the better the results is also borne out by a comparison of results to the height of the resection. This is especially true on the left side.[12] Table 1 makes this evident

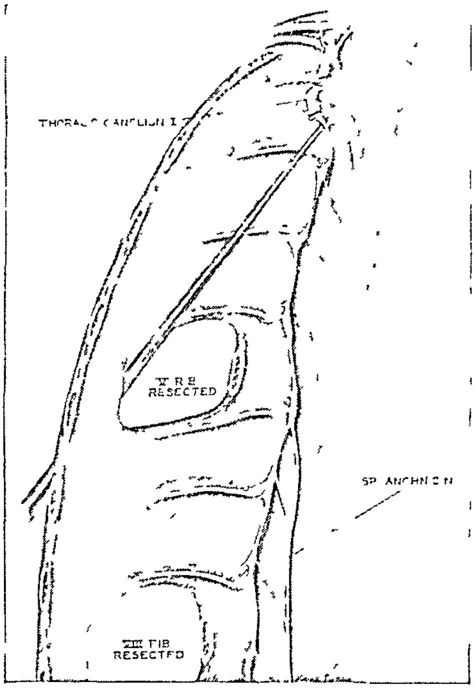

Fig 2.—The upper end of the sympathetic resection

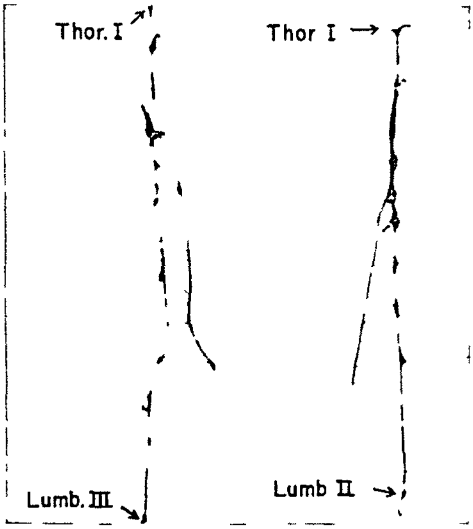

Fig 3.—Specimens removed in sympathectomy from the stellate ganglion to the third lumbar ganglion (hypertension with severe angina).

TECHNIC OF OPERATION

The technic used for the removal of the stellate ganglion and the thoracic sympathetic ganglion chain is identical to the procedure previously described[13] for extensive combined thoracolumbar sympathectomy, except that the incision is extended cephalad approximately 4 cm. The medial portion of the fifth rib is removed as well as the eighth and eleventh ribs instead of the seventh and eleventh ribs as previously described. This allows excellent extrapleural exposure of the upper thoracic sympathetic chain and ganglions as indicated by figure 2. The entire thoracic sympathetic system including the stellate ganglion may be removed in this manner (fig. 3).

GENERAL RESULTS

High thoracolumbar sympathectomy (table 2) was performed in a series of 10 hypertensive patients with severe disabling angina pectoris, among whom only one had had probable coronary infarction (case 8) but all presumably had coronary insufficiency. The follow-up period was from three months to three years. Complete relief except for a residual sensation of constriction in the throat was obtained in five, or one half of the cases. There was partial but satisfactory relief of pain in the remaining five patients. One of the latter group, referred to Dr. Poppen for operation by Drs Joslin and Root, was bedridden with status anginosus. Merely turning in bed produced pain. Although she still suffers mild substernal pain, causing her to stop to rest, she is active, doing all her housework and going on shopping trips (case 5).

Table 1.—*Results in Relation to Height of Resection*

Complete Relief			Partial Relief		
Case	Left	Right	Case	Left	Right
2	T_1	T_3—Throat	1	T_3	T_0—Left side of neck, fingers
4	T_2	T_2	3	T_3	T_1—Left arm, throat (seldom)
8	T_1	T_1—Throat, jaw	5	T_2	T_4—Substernal pain on moderate exertion; complete relief of status anginosus
9	T_2	T_2—Throat	6	T_2	T_1—Hot sensation in arms, throat
10	T_1	T_4	7	T_2	T_4—Left side of chest, throat (mild)

In table 3 is listed the progressive relief of anginal pain in successive reports from the Lahey Clinic on results of splanchnicectomy for hypertension.

The patients in series 4 all had severe disabling angina. Milder angina has so often been relieved by resection to the fourth thoracic level that we have not subjected these patients to resection of the first thoracic ganglion with its additional technical difficulties and danger of ptosis.

In series 1 patients with anginal pain were not selected for surgical treatment. In series 2 and 3 no careful note was made of whether the patient still had partial or complete relief. The pattern of the pain when it did recur was never noted as having been changed, as it invariably is when all or part of the anginal pathway is resected. There was no operative mortality in the 10 patients in series 4. One patient died three years later of a coronary infarction (case 1). One other patient has survived three years, and three have survived two years.

COMMENT

All our patients had fairly severe symptoms of postural hypotension for about six months postoperatively, but only the most severely ill patient, who had status anginosus (case 5), experienced angina on standing up quickly. Resection in this case was limited to the second thoracic ganglion on the left and the fourth thoracic ganglion on the right. It might be expected that decreased coronary flow resulting from rapid severe drop of blood pressure on standing would increase the incidence of angina in the hypertensive patient. The fact that this seldom occurs is an argument in favor of the possibility that abolition of the cardiac sympathetic pathway actually increases coronary flow. The principle of the reflex sympathetic dystrophy type of pain and the theory of the internuncial pool of Lorente de No[14] may account for the success of the operation. That some such mechanism may pertain is further borne out by the improvement of a Dupuytren's contracture in the left hand of one patient (case 9) in whom resection was carried out to the first thoracic ganglion on the left, while the Dupuytren's syndrome on the right hand became worse when resection was only to the level of the third thoracic sympathetic ganglion. Kehl[15] reported six cases of Dupuytren's contracture following coronary disease and infarction. We suggest that good results might be expected in cases of the shoulder-hand syndrome, a rather rare complication of coronary artery disease described by Hilker.[16] Johnson[17] reported that hand changes take place in 21.8 per cent of patients with myocardial infarction, suggesting a reflex sympathetic dystrophy induced by cardiac pain. These observations enhance the rationale of sympathectomy for anginal pain.

---

[12] These operations being splanchnicectomies for hypertension, it is to be understood that the lower end of resection was the second or third lumbar ganglions bilaterally.

Table 2.—*Summary of Cases*

Case	Age	Sex	Preoperative Status	Level of Operation	Time of Follow-up	Present Status	Result
1	42	F	Grade 3 hypertension; pain in right chest and arm on exertion	Left: T_3-L_2 Right: T_6-L_2	3 yr.	Experienced immediate relief of pain, but it recurred on the right; died 9/11/49 of coronary occlusion	Partial relief
2	46	F	Grade 2 hypertension; substernal pain on exertion	Left: T_1-L_2 Right: T_3-L_3	3 yr.	No angina	Complete relief, except throat
3	47	F	Grade 2 hypertension; exertional anginal pain	Left: T_3-L_2 Right: T_1-L_2	2 yr., 8 mo.	Occasional pain in throat and left arm on exertion	Partial relief
4	41	M	Grade 3 hypertension; substernal pressure on exertion	Left: T_2-L_2 Right: T_2-L_2	2 yr., 9 mo.	No angina	Complete relief
5	49	F	Diabetes mellitus; grade 3 hypertension; angina decubitus and status anginosus	Left: T_2-L_2 Right: T_4-L_2	2 yr., ...	No longer bedridden but has substernal pain on exertion and on standing quickly; complete relief of status anginosus	Partial relief
6	42	M	Grade 3 hypertension; persistent angina of effort despite previous T_7-L_1 resection	Left: T_2-T_9 Right: T_1-T_7	20 mo.	No precordial pain but an occasional hot sensation in throat and arms	Partial relief
7	49	F	Grade 2 hypertension; substernal smothering, pain on exertion	Left: T_2-L_2 Right: T_4-L_2	15 mo.	No angina for 1 yr. but in last 3 mo. return of some chest pain on exertion and choking sensation in throat	Partial relief
8	54	F	Grade 3 hypertension; substernal pain on exertion	Left: T_1-L_2 Right: T_1-L_2	1 yr., 4 mo.	No angina; bilateral subacute subacromial bursitis developed	Complete relief, except throat and jaw
9	45	M	Grade 2 hypertension; bilateral Dupuytren's contracture; angina of effort	Left: T_1-L_3 Right: T_3-L_2	6 mo.	No pain, only a sense of constriction in throat on exertion; Dupuytren's contracture better on left, worse on right	Complete relief, except throat
10	44	F	Grade 2 hypertension; dull, squeezing, substernal pain on exertion	Left: T_1-L_2 Right: T_4-L_2	3 mo.	No pain	Complete relief

Another disadvantage of the operation besides the ptosis of Horner's syndrome, postural hypotension and severe sweating in the groins is swollen nasal membranes (noted by Grimson and others[9]). This last complaint occurred in two of our patients, but it tends to subside early.

That coronary irrigation may actually be increased in much the same way as in a desympathectomized limb is suggested by the increased capacity of these patients for work, before the residual throat constriction symptom of angina occurs. For example, in case 8 the patient had hypertension grade 3 and probably remote anterolateral myocardial infarction. For the past 18 months she had been incapacitated and unable to do any housework or to walk in cold weather. Sixteen months after resection of the first thoracic to the second lumbar sympathetic ganglions on the left and the third thoracic to the second lumbar ganglions on the right she reported a new sensation of pain in the throat, radiating to both lower jaws. This pain was so unfamiliar to her and so different from her old angina pain that she attributed it to a small, nontoxic, colloid, adenomatous goiter and thought its removal might help. Only on careful questioning did it become apparent that this pain also occurred on effort but only after much greater exertion than that required to cause pain before operation. In fact she now does all her housework and goes shopping in any weather. Her blood pressure was still 230 mm. systolic and 110 mm. diastolic as compared to 250 mm. systolic and 124 mm. diastolic before operation. It was almost one and a half years after operation; she had had no intervening coronary attacks, so the extended exercise tolerance could not be attributed to reduction of cardiac load, prolonged rest after

Table 3.—*Comparison of Relief of Anginal Pain in Four Series of Cases*

	Number of Persons with Angina	Height of Resection	Satisfactory Relief, Percentage
Series 1..................	0	T_{12}-L_2 or L_3	(Angina patients were avoided)
Series 2..................	8	Between T_{12} and T_5-L_2	12.5
Series 3..................	15	T_4	73.0
Series 4..................	10	Various parts of anginal pathway	100.0

operation or the relief of effort angina that sometimes comes after a coronary infarction. White and Bland[4] have successfully abolished residual jaw pain by mandibular nerve injection.

Another possible argument in favor of increased coronary flow after desympathectomizing the heart is seen in case 3. This patient's electrocardiographic exercise tolerance test changed from positive to negative. She wrote in her letter "I feel much better, do more work, have adopted a baby and am kept very busy." She still has occasional pain in the throat and left arm on exertion two years and eight months after resection of the third thoracic to the second lumbar ganglions on the left and the first thoracic to the second lumbar ganglions on the right.

The disappearance of the throat constriction together with all pain in two patients is probably the result of extension of exercise tolerance incident to increased coronary flow rather than of resection of any pain pathway mediating a sense of throat constriction.

In case 1, in which the patient died three years after operation, results were the poorest of all; unfortunately the patient had resection only to the sixth thoracic ganglion on the right, although her pain preoperatively was mostly right-sided. Sweating could be demonstrated over the right side of the chest and the right arm after operation, proving that the most important pathway in this case was not touched at all. Our experience with this patient bears out White's[4] contention that cardiac pain is mediated to the right by the right cardiac nerves and to the left by the left cardiac nerves.

Case 6 is of interest because the patient had resection to the seventh thoracic ganglion in 1943 but still had angina. When he underwent operation again for angina and persistent hypertension he obtained gratifying relief from resection to the second thoracic on the left and the first thoracic on the right.

In case 7 the patient is classed as obtaining partial relief although she had complete relief for a year. Her recurrence in the last three months may be due to regeneration of the neural pathways, but she has not yet been subjected to a sweat test to determine this point.

CONCLUSIONS

1. Resection of various parts of the sympathetic anginal pathway (first to the fourth thoracic on the right and left) resulted in satisfactory relief of anginal pain in all 10 patients. Relief was complete in five except for a residual sense of throat constriction in three.

2. Resection of the anginal pathway should include the first to the fourth thoracic ganglions on both sides for best results.

3. There is not always residual throat or jaw pain, but relief from this may result because (*a*) exercise tolerance is improved by lessened strain on the heart from hypertension and (*b*) actual dilation of the coronary bed occurs.

4. The pernicious circle of anginal pain in status anginosus can be broken by sympathectomy, probably on the same basis that reflex sympathetic dystrophy is helped.

5. Horner's syndrome is not a valid contraindication to carrying the resection to the lower stellate ganglion (first thoracic), especially when the resection is bilateral.

HORMONE STUDIES IN PEPTIC ULCER

Pituitary Adrenocorticotropic Hormone (ACTH) and Cortisone

For some time we and our associates[1] have been interested in a possible pituitary-gonadal mechanism in the pathogenesis of peptic ulcer.[1b] Several clinical observations tend to support this thesis: first, peptic ulcer and its complications are less common in women than in men; second, pregnancy usually has a beneficial effect on symptoms of peptic ulcer; third, although peptic ulcer in children is rare, its incidence is equal in both sexes until maturity, when the incidence again becomes higher in the male; fourth, peptic ulcer in women not infrequently has its onset during the climacterium; fifth, the menopause may be expected to aggravate symptoms of ulcer, and sixth, a fairly high percentage of women with proved duodenal ulcer apparently show an endocrine imbalance. It should also be noted that during the reproductive years the anterior pituitary gland is more active in the female than in the male and that it hypertrophies during pregnancy. We postulated the existence of a sex-linked endocrine mechanism, with increased production of pituitary hormones, as the means by which the normal woman is protected against peptic ulcer during her reproductive decades Supportive evidence for this belief was found in dogs

with Mann-Williamson ulcers.[1a,b] The anterior pituitary hormones (luteinizing and follicle stimulating), the corpus luteum hormone (progesterone) and urine extracts from pregnant and nonpregnant women (uroanthelone) appeared to be of significant value in preventing or healing these ulcers, but estrogens were without benefit.

A new approach to this study of sex-endocrine relationships was suggested by Hench's successful use of pituitary adrenocorticotropic hormone (ACTH) and cortisone in rheumatoid arthritis,[2] that is, the added possibility of primary or intermediate activity of the adrenals in the pathogenesis of ulcer. Hench's use of these hormones was predicated on observations that both pregnancy [3] and jaundice [4] have an ameliorating influence on rheumatism. Since pregnancy, as a rule, relieves the symptoms of peptic ulcer as well as those of rheumatoid arthritis, one might assume that the same pituitary-adrenal hormone mechanism would be active in both diseases. Therefore, we have attempted to determine what effect, if any, these hormones might have on experimental Mann-Williamson ulcers in the dog. We also studied the urinary excretion of 17-ketosteroids and 11-oxycorticosteroids in both normal subjects and patients with duodenal ulcer. We wish to report our preliminary data and also our observations on the treatment of four ulcer patients, two with pituitary adrenocorticotropic hormone and two with cortisone.

EFFECT OF HORMONES ON EXPERIMENTAL ULCERS

Experimental ulcers in dogs were produced by the Mann-Williamson operative technic,[5] sometimes referred to as surgical duodenal drainage.[6] This operative technic was chosen because the jejunal ulcer which ensues closely simulates, macroscopically and microscopically, the postoperative jejunal ulcer in man.

The present series involves 23 Mann-Williamson dogs: 11 control animals; 6 treated with cortisone and 6 treated with pituitary adrenocorticotropic hormone. The weight of the animals ranged between 20 and 25 pounds (9 and 12 Kg.). Treatment with cortisone was started 13 to 30 days after the operation and continued daily throughout the life of each animal. The dogs received 20 mg. of cortisone acetate subcutaneously or intermuscularly daily in two equally divided doses. The drug was administered as a sterile saline suspension containing 1.5 per cent benzyl alcohol as a preservative. Treatment with pituitary adrenocorticotropic hormone was started eight to 35 days after the Mann-Williamson operation and continued daily through the life of the animals. The hormone was administered subcutaneously or intramuscularly in doses of 10 to 15 mg. a day divided into two equal doses (Armour standard LaTA or its equivalent). Final and detailed results will be reported later, since the study is not yet complete. However, on the basis of our data to the time of writing the following preliminary summary may be made:

1. Shortly after operation, control dogs began to lose weight, showed signs of weakness and appeared chronically ill in most instances We noticed some improvement in the dogs treated with pituitary adrenocorticotropic hormone. As a group the cortisone-treated dogs were in good condition, continued in a state of excellent nutrition and showed their usual vigor and activity.
2. The average postoperative survival time of the cortisone-treated animals was twice that of the control animals and about 40 per cent longer than that of the animals treated with the pituitary hormone. To date, only one of the 11 control animals survived six months after the operation. However, two of the six animals treated with pituitary adrenocorticotropic hormone and four of the six cortisone-treated animals were alive at the end of six months.
3. This beneficial effect of cortisone and to a lesser degree of pituitary adrenocorticotropic hormone on the postoperative survival time of Mann-Williamson dogs is similar to that obtained by using an extract prepared from urine of pregnant mare (uroanthelone, kutrol®) and given orally. Three of seven Mann-Williamson dogs so treated are still alive and in an excellent nutritional state 6, 8 and 10 months after surgical intervention The beneficial effect obtained is therefore not associated with cortisone alone. The effects of these hormones on ulcers and other tissues and organs will be reported in detail elsewhere One striking effect is the pronounced reduction in the postoperative visceral adhesions in the cortisone-treated and adrenocorticotropic hormone-treated Mann-Williamson dogs as compared with those found in the untreated animals.

Comment.—The average survival time of Mann-Williamson dogs treated with cortisone is longer than that of the animals given pituitary adrenocorticotropic hormone and considerably longer than that of the untreated animals. The treated animals, as a group, were in an exceptionally good nutritional state and in good vigor. However, similar results have been obtained with an extract from pregnant mares' urine (hormonal products).[7]

URINARY EXCRETION OF 11 OXYCORTICOSTEROIDS AND 17-KETOSTEROIDS

Material and Method.—Because it is generally accepted that urinary excretion of 11-oxycorticosteroids [8] and 17-ketosteroids [9] is a measure of adrenal activity, we compared the urinary excretion of these products in 31 normal subjects (16 males and 15 females) with the excretion in 43 patients with duodenal ulcers (31 males and 12 females). Ages in both groups of subjects ranged between 20 and 66 years. In 12 of the ulcer patients steroid excretion was studied during an ulcer attack and again months later, when they were in a period of remission.

Both ambulatory and hospitalized patients were included. All had the typical ulcer syndrome and roentgenologic evidence of ulcer. Both groups (the normal subjects were all ambulatory) were carefully briefed in the method of collecting 24-hour urine excretions. Chloroform was added to the bottles as a preservative before collection was started. The complete 24-hour urine output for each subject was delivered to the laboratory on the morning the collection was completed. In every case the initial extraction was begun within eight hours after the urine was received in the laboratory.

[5] The operative procedure is as follows: Transection of the pylorus, closure of the duodenal stump, transection of the jejunum 4 inches (10 cm) beyond the ligament of Treitz, end to side gastrojejunostomy and side to side jejunoileostomy, anastomosing the proximal curved portion of the jejunum to the ileum 10 inches (25 cm) above the ileocecal valve This short circuits the bile, pancreatic juice and duodenal secretion into the terminal ileum The acid gastric juice and gastric contents enter the jejunum

[7] The term anthelone is applied in an all inclusive sense to extracts of urine and intestinal mucosa having antiulcer properties Anthelone agents have been prepared from a number of sources including urine, human or other, (uroanthelone) and hog intestine (enteroanthelone, previously referred to as enterogastrone concentrates).

[8] The 11 oxycorticosteroids are organic compounds which contain the fundamental nuclear framework of the perhydrocyclopentenophenanthrene ring system, in common with the sterols, bile acids and sex hormones They are further differentiated from the other adrenal corticosteroids by the presence of an oxy or hydroxy radical on C 11 These substances have a specific effect on protein and carbohydrate metabolism, in contrast to the corticosteroids, which lack an atom of oxygen on C 11 and which have a specific effect on water and electrolyte metabolism

[9] The 17-ketosteroids also contain the fundamental nuclear skeleton of the same perhydrocyclopentenophenanthrene ring system These compounds receive their name because of the presence of a ketone group on C 17. They are produced by both the adrenal cortex and the testes Many exhibit androgenic activity, but others are biologically inert

The 11-oxycorticosteroids were determined by the chemical method of Daughaday, Jaffe and Williams,[10] which depends on measurement of the formaldehyde liberated by the hormone on oxidation with periodic acid. An aliquot of an unhydrolyzed 24-hour urine specimen is acidified and extracted with chloroform at room temperature. Partition of the extract between benzene and water adds to the specificity, and a distillation step separates the formaldehyde from interfering chromogens before color development with chromotropic acid.

The 17-ketosteroids were determined by the rapid chemical method of Robbie and Gibson,[11] which consists essentially of acid hydrolysis of an aliquot of a 24-hour urine specimen, followed by carbon tetrachloride extraction. The hormone content is then assayed by the alkaline *m*-dinitrobenzene technic.

Average 1.35 mg./24 hr.			Average 0.91 mg./24 hr.		

Results.—Table 1 presents the 24-hour urinary excretion of 11-oxycorticosteroids in each of the 31 normal healthy adult subjects and in each of the 43 patients with active duodenal ulcer. Table 2 shows the average excretion of both the 11-oxycorticosteroids and the 17-ketosteroids for the two groups of subjects.

Normal Subjects: 1. Average 11-oxycorticosteroid excretion for the normal subjects is 1.35 mg. (males 1.25 mg. and females 1.46 mg.).

2. Average 17-ketosteroid excretion for the normal subject is 9.6 mg. per 24-hour urine sample (males 10.9 mg. and females 8.3 mg.). The higher excretion in the males is expected because of the role played by the testis in the production of a portion of these compounds.

Ulcer Patients: 1. The average 11-oxycorticosteroid excretion for the ulcer patients is 0.91 mg. (males 0.88 mg. and females 1.00 mg.). Seventy per cent of patients had values below 1.0 mg., but only 19 per cent of normal subjects had such low determinations. Thirty-five per cent of the ulcer patients excreted less than the lowest average normal figure (0.74 mg.). These lower values are statistically significant (table 3).

Table 2.—*Average 24-Hour Urinary Excretion of 11-Oxycorticosteroids and 17-Ketosteroids*

Group	11-Oxycorticosteroids Mg./24 Hr.		17-Ketosteroids Mg./24 Hr.	
1 Normal subjects (31)				
Male 15	1.25	1.35	10.9	9.6
Female 16	1.46		8.3	
2 Patients with active duodenal ulcer (43)				
Male 31	0.88	0.91	9.8	8.5
Female 12*	1.00		5.3	
3 (*a*) 12 patients in group 2 during active symptoms	....	0.90	...	8.2
(*b*) The same 12 patients while symptom free	....	1.14	...	6.6

* These are the same patients (*a*) during periods of ulcer distress and (*b*) during periods of remission. They are also included in group 2.

2. The average 17-ketosteroid value for the ulcer patients is 8.5 mg. in a 24-hour urine output (males 9.8 mg. and females 5.3 mg.).

3. Of interest is the average steroid excretion of 12 ulcer patients during periods of remission as compared with periods of ulcer distress. It will be noted from table 2 that during active ulcer symptoms patients excreted an average of 0.9 mg. of 11-oxycorticosteroids in 24 hours. When these 12 patients were symptom free, months after the ulcer attack, they excreted on the average 1.14 mg. Variations in 11-oxycorticosteroid excretion are also statistically significant (table 3).

The average excretion of 17-ketosteroid was slightly higher during periods of ulcer distress (8.2 mg. during symptoms and 6.6 mg. during symptom-free intervals).

Comments.—In patients with active duodenal ulcer 11-oxycorticosteroid excretion is less than in normal healthy subjects. The difference is statistically significant. These data are presented to stimulate additional comparative studies not only for larger series of ulcer patients but also for patients with other chronic gastrointestinal diseases. The latter group of patients might also show similar low levels. We are studying this possibility now.

Table 3.—*Statistical Analysis of 11-Oxycorticosteroid Values for Significance*

Class	No.	Mean	S.D. Mean	Diff.	S.D. Diff.	t	P*
1 Normal male	15	1.2175	±0.0848	0.3653	±0.1104	3.31	<0.01
Ulcer male	31	0.8522	±0.0706	......	....	....	....
2 Normal female	16	1.4846	±0.1487	0.4821	±0.1780	2.71	0.01
Ulcer female	12	1.0025	±0.0978				
3 12 ulcer patients in and out of ulcer attacks	In 12 patients observed in and out of attacks, the mean difference was 0.2375 lower in attack than out. The standard deviation of this mean was 0.111, giving a t value of 2.14 and a P of <0.05.					2.14	<0.05

* Interpretation of P values: If P is 0.05 or <0.05, the result is statistically significant; if 0.01 or <0.01, statistically highly significant, and if >0.05, not statistically significant.

TREATMENT OF PATIENTS WITH HORMONES

Thus far we have treated two patients with cortisone (cases 1 and 2) and two with pituitary adrenocorticotropic hormone (cases 3 and 4).

Case 1.—*History and Previous Course.*—Miss V. E., aged 33, had an ulcer history dating back to 1940. During the six years prior to the present observation (1943-1949) she had frequent relapses, remaining symptom free for only two to three months at a time. During the past two years (1947-1949) distress recurred almost daily. For the last year it was more acute, so that the patient worked below her normal efficiency. During this period there was a weight loss of about 15 pounds (6.8 Kg.). Relief followed food and antacids for only one-half to one hour. Nocturnal distress was constant during the past six months, but there was no back pain. There was frequent nausea but no vomiting.

---

[10] Daughaday, W. H.; Jaffe, H., and Williams, R. H.: Chemical Assay for "Cortin": Determination of Formaldehyde Liberated on Oxidation with Periodic Acid, J. Clin. Endocrinol. 8: 166 (Feb.) 1948.

[11] Robbie, W. A., and Gibson, R. B.: Rapid Clinical Determination of Urinary 17-Ketosteroids, J. Clin. Endocrinol. 3: 200 (April) 1943.

When we saw the patient in June 1949, she was started on conservative ambulatory ulcer management consisting of the usual bland foods, frequent feedings, antacids and antispasmodics. With more rest and reassurance she soon became symptom free and continued in remission (except for occasional mild distress, either during the day or night) for a period of approximately five months, when she had another relapse. More rigid ambulatory management failed, and hospitalization followed for a period of two weeks, with the patient on an hourly feeding schedule of milk and cream (which was gradually increased), frequent antacids, antispasmodics, aspiration, and stomach lavage at bedtime. The patient responded to therapy, but within six weeks after discharge she again had a relapse. On her return to the hospital (February 1950) she improved again, but the ulcer symptoms did not disappear completely.

Clinical and Laboratory Data.—Physical examination was essentially noncontributory except for moderate tenderness in the epigastrium and the right upper abdominal quadrant. Repeated cholecystography revealed a normally functioning gallbladder. The gastrointestinal roentgenologic study showed "a spasm of the duodenal bulb associated with a pocket of barium presenting the usual characteristics of an ulcer crater."

Results of all laboratory procedures were within normal limits. These included the following: complete blood counts, determination of nonprotein nitrogen, total proteins, albumin and globulin ratio, blood uric acid, cholesterol and cholesterol esters, alkaline phosphatase, sodium, potassium, sedimentation rate and eosinophil count (direct method). The urine examination, in addition to routine studies, included uric acid, creatinine and creatine determinations. A five hour glucose tolerance test was also within normal limits. The basal metabolic rate was −1 per cent. The electroencephalogram was also normal, as was the electrocardiogram. The urine 11-oxycorticosteroid level prior to cortisone administration was 0.9 mg. per 24-hour excretion on the first occasion and 1.68 on the second. The 17-ketosteroids were 10.1 mg. per 24-hour excretion on the first examination and 8.6 on the second. Gastric contents obtained by continuous suction during a seven hour nocturnal secretion study prior to cortisone therapy consisted of 497 cc. with free hydrochloric acid output of 386 mg.

Treatment and Course.—The patient received cortisone for 11 consecutive days. During the first two days the dosage was 100 mg. twice daily and from then on 100 mg. daily. A total of 1,300 mg. of cortisone was administered. The patient's response was remarkable during cortisone therapy. Not only did her ulcer symptoms completely disappear but she had a sense of well-being, stating, "I feel better than at any time during the last ten years." Appetite and weight increased. Prior to cortisone therapy she had considerable dysmenorrhea, but this condition has disappeared completely (nine months follow-up).

All examinations enumerated above were repeated on the morning of the sixth day of cortisone therapy and on the following morning after cortisone was discontinued. Significant changes were noted as follows:

1. Urine 11-oxycorticosteroids became moderately elevated during cortisone administration and fell to within normal limits shortly after the drug was discontinued. The highest value was 2.6 mg. per 24-hour excretion (on the sixth day of treatment). The 17-ketosteroids showed no significant change.

2. The seven-hour nocturnal gastric secretion (after cortisone was discontinued) was 486 cc. with 726 mg. of free hydrochloric acid (compared with 497 cc. of secretion and 386 mg. of free acid prior to treatment).

3. The roentgenologic study (on the third day after discontinuance of cortisone therapy) revealed persistence of a small ulcer crater in the central portion of the duodenal bulb in the same site as that demonstrated in previous examinations. It was smaller than it had been previously. There was no associated pylorospasm and little tenderness on pressure.

Comment.—Shortly after injections of cortisone were given, a symptom-free interval began in a patient who had previously been totally intractable to conservative ulcer management. One cannot be certain that all the improvement was due to cortisone, but the general well-being of the patient might certainly be credited to this hormone. Nine months after her discharge the patient is entirely symptom-free and is attending to her usual duties with normal efficiency. She had not been able to live with this degree of comfort for at least a year and a half before the cortisone treatment.

Case 2.—*History and Previous Course.*—Mr. M. P., aged 52, had an ulcer history dating back to 1930. After hospitalization for five days in 1930 the patient was symptom free for six years. He failed to respond to ambulatory management during his second attack (in 1936), but with hospitalization he again became symptom free and remained well for one year. He had a mild hemorrhage in 1937 and again in 1946. Since 1946 he has had relapses annually every spring and fall.

When this patient was seen Jan. 17, 1950 he had had epigastric distress and continuous day and night pain for a period of three weeks, unresponsive to self medication consisting of hourly feedings and nonabsorbable antacids. He was hospitalized Jan. 21, 1950 and given small hourly feedings with antacids and antispasmodics, and gastric lavage at midnight. He failed to improve during a seven day stay and left the hospital against advice. Because of continuous distress he was readmitted Feb. 19, 1950. Food and antacids produced relief for only 15 to 30 minutes at a time. He experienced frequent nocturnal distress but had no back pain. There was no nausea or vomiting. The stools (normal color) gave a positive reaction to the benzidine test for occult blood.

Clinical and Laboratory Data.—Physical examination, routine laboratory studies and cholecystography were essentially noncontributory. Roentgenologic study of the upper part of the alimentary tract showed "a marked deformity with contracture of the duodenal bulb incident to scarring from an old duodenal ulcer. The marked deformity of the bulb was about the same as it had been when the patient was examined in 1946. Transit of the meal was normal for a three hour period, and the stomach emptied in this time. Palpation over the duodenal bulb elicited no pain. There was, however, some spasm of the bulb."

When the patient again failed to respond to hospital management he was advised to have a subtotal resection. The diagnosis was a posterior wall duodenal ulcer which had penetrated (or perforated) the pancreas. However, we decided to attempt cortisone therapy before resorting to surgical intervention.

The blood studies, urine studies and other examinations enumerated in the report on case 1 were again within normal limits on this patient. Gastric contents obtained by continuous suction during a seven-hour nocturnal secretion study amounted to 476 cc. with a free hydrochloric acid output of 908 mg. Test for 11-oxycorticosteroids showed 1.06 mg. per 24-hour urine volume during the first precortisone study and 1.1 mg. for the second; tests for 17-ketosteroids showed 7.3 mg. per 24-hour urine output during the first study and 7.6 for the second.

Treatment and Course.—As in case 1, this patient received cortisone for 11 consecutive days: 100 mg. twice daily for the first two days and once daily for nine days, a total of 1,300 mg. The patient failed to respond to treatment. He continued to have distress not unlike that which he experienced before he had received cortisone.

Significant changes were apparent in laboratory examinations made on the sixth day of cortisone therapy and on the morning after cortisone was discontinued. (All other determinations were within normal limits):

1. Urinary 11-oxycorticosteroids became moderately elevated during therapy and fell to normal limits shortly after cortisone was discontinued. The highest values were 3.5 mg. on the fourth day and 3.4 mg. on the seventh day. Values for 17-ketosteroids were also moderately elevated, reaching a peak of 12.4 mg. during the sixth day of therapy and remaining between 10 and 11.9 mg. throughout the remaining period of treatment, with a fall to precortisone levels on the second day after treatment was discontinued.

2. The eosinophil count dropped below 50 per cent of the precortisone level on the fifth day and remained below the 50 per cent level throughout the period of treatment.

3. After cortisone was discontinued the seven-hour nocturnal gastric secretion was 683 cc., with 1,995 mg. of free hydrochloric acid, compared with 476 cc. (with 908 mg.) in the precortisone period.

4. The serum alkaline phosphatase was moderately elevated.

The patient was subjected to subtotal resection three days after cortisone was discontinued (March 8, 1950). The surgeon reported that: "The first portion of the duodenum was decidedly deformed and so densely adherent to the head of the pancreas that it could not easily be dissected free. With a finger inside the duodenum, the examiner found a deep posterior ulcer about ¾ inch (2 cm.) distal to the pyloric ring, at which point there was also a high degree of obstruction. The ulcer had penetrated into the head of the pancreas, which formed the base of the ulcer. The liver, gallbladder, spleen and pancreas were grossly normal." Subtotal gastric resection was done. The patient made an uneventful recovery.

Comment.—This patient failed to respond to cortisone therapy; symptoms were neither aggravated nor improved. At surgical intervention, a long-standing, chronic posterior wall duodenal ulcer was found, which had penetrated deeply into the pancreas.

CASE 3.—*History and Previous Course.*—Mr. W. P., aged 36, presented an ulcer history since 1937, with frequent relapses and short symptom-free intervals. He had had three episodes of melena and one of hematemesis. During the eight months prior to observation he had daily experienced epigastric pain which was only moderately relieved with food and antacids. Distress occurred every two hours during the night. There was no back pain and no nausea or vomiting. He had refused and never followed a routine ulcer regimen.

When we saw him Jan. 4, 1949 physical examination and routine laboratory tests revealed essentially normal conditions. Cholecystography showed a normally functioning gallbladder without any evidence of calculi. The roentgenologic study of the gastrointestinal tract demonstrated "a small barium-filled ulcer niche at the base of the bulb on the lesser curvature side, with a persistent deformity of the duodenal cap."

The patient refused to follow a restricted diet. Antacids, antispasmodics and discussion therapy failed to initiate a symptom-free interval. He refused hospitalization. After a year of procrastination, and after a period of three months of practically continuous distress day and night, he entered the hospital April 12, 1950, when our usual ulcer regimen was instituted: bed rest, hourly feedings of milk and cream, frequent antacids and antispasmodics, sedatives, vitamins, gastric aspiration and lavage at bedtime, and reassurance.

A repeat roentgenologic examination at this time showed "transient pylorospasm. No ulcer crater could be seen in the duodenal bulb when barium did fill this structure. Some mild scarring was well demonstrated on the roentgenograms. Three-hour study showed no disturbance in the gastric emptying or in the small bowel motility."

Treatment Regimen.—After seven days of hospital management the distress of the patient was less pronounced but was still present. It was our impression that the patient had a posterior wall duodenal ulcer which had penetrated (or perforated) the pancreas. A subtotal gastric resection was advised, but pituitary adrenocorticotropic therapy was instituted before the decision to resort to surgery. The drug was administered intramuscularly in a dosage of 100 mg. daily (33.3 mg. every eight hours). It was our intention to treat the patient daily for 12 consecutive days, but because his distress became more acute (even more acute than that experienced prior to his hospital admission) the regimen was discontinued after nine days.

The following examinations were made on the urine daily for five days prior to hormone therapy, daily during the nine days of treatment and daily for five days after the drug was discontinued: volume of 24-hour urine, 11-oxycorticosteroids, 17-ketosteroids, sodium, potassium, nitrogen, calcium, phosphorus, chlorides, uric acid, creatinine and creatine.

The following examinations were made on the blood twice before hormone treatment was instituted, on the morning of the sixth day of treatment and on the first and fourth mornings after treatment was discontinued: total proteins with albumin and globulin ratio, uric acid, alkaline and acid phosphatase, sodium, potassium, calcium, sodium chloride, phosphorus, cholesterol and cholesterol esters, fasting blood sugar and glutathione.

An eosinophil count was made daily throughout the period of study, as was also a routine blood count. In addition, the following tests were done once before and twice after hormone treatment: a five-hour glucose tolerance test; an electrocardiogram, an electroencephalogram and a basal metabolic rate determination. A seven-hour nocturnal gastric secretion study was done only once, before hormone therapy, the patient refusing the posthormone study.

Clinical Course.—During the first four days of pituitary adrenocorticotropic therapy, the symptoms were not unlike those experienced by the patient during the three days immediately preceding treatment, i. e., mild ulcer distress two or three times daily (about one hour after intake of food) and once during the night. However, on the fourth day of hormone therapy, in addition to the epigastric distress the patient had pain in the upper right abdominal quadrant. The epigastric pain became more acute, recurred much more frequently, lasted much longer and was not relieved by food and antacids, as it had been before treatment with the hormone was instituted. In addition the patient became "tired, very restless and sleepy," with a feeling of "exhaustion."

At first, the physical findings were not appreciably changed except for tenderness in the epigastrium and right upper quadrant. However, on the fifth day there was definite resistance and muscle spasm to the right of the midepigastrium. There was no nausea or vomiting. Hourly feedings of milk and cream with frequent administration of an aluminum hydroxide preparation were reinstituted, but symptoms continued unabated. At times, because of acute epigastric pain, morphine and atropine (in the usual dosage) had to be administered.

On the seventh day of therapy, freckling pigmentation was noted on the left side of the face and the right side of the neck. On the morning of the ninth day in spite of increasing "exhaustion" of the patient, the systolic blood pressure, which previously had ranged between 120 and 130 mm., increased to 150 mm. and the diastolic, previously between 70 and 80 mm., increased to 110 mm. The epigastric and right upper quadrant distress increased in severity. There developed an area of severe muscle spasm and exquisite tenderness to the right of the umbilicus. The symptoms and physical findings were those of impending perforation and localized peritonitis. The hormone was then discontinued (at the end of the ninth day of treatment).

Twenty-four hours after the discontinuation of hormone therapy the patient began to improve. The right upper quadrant distress disappeared, as did the tenderness and muscle spasm. The epigastric distress also subsided to the pretreatment level, with resultant relief of the patient's symptoms for short periods on feedings and antacids. The patient generally became more relaxed and began to regain his strength and sense of well-being. The blood pressure returned to normal levels, and the freckling pigmentation of the skin disappeared two weeks later.

Because ulcer distress continued a subtotal gastric resection was performed on the sixth day after pituitary adrenocorticotropic therapy was discontinued. "The duodenum was chronically thickened with some adhesions, the area of greatest thickening being about ½ inch (1.27 cm.) distal to the pyloric ring and close to the superior margin. When the stump of the duodenum was held open an ulcer almost 1 cm. in diameter was demonstrated on the posterosuperior wall attached to the top of the pancreas. Gastric resection was performed."

There was a decided response to administration of the hormone, as indicated by the following laboratory data:

1. The urinary excretion of 11-oxycorticosteroids and 17-ketosteroids increased appreciably throughout the period of hormone administration, the former reaching a peak of 8.7 mg. and the latter 55.8 mg. during the 24 hours of the sixth day.

2. The eosinophil count dropped to below the 50 per cent level 24 hours after therapy was instituted. Throughout the remaining eight days of therapy the eosinophil count ranged from zero to 14 (the latter only on one occasion).

3. The urine uric acid—creatinine ratio increased moderately.

4. Before therapy the serum albumin determination was 3.93 Gm. and the globulin 2.13 Gm. per 100 cc. (a ratio of 1.8 to 1). On the morning after the hormone was discontinued the serum albumin was 3.45 Gm. and the globulin 3.07 Gm. (a ratio of 1.12 to 1). On the morning of the fourth day after therapy was discontinued there was a definite reversal of the albumin-globulin ratio (albumin 2.6 Gm. and globulin 4.17 Gm., a ratio of 0.64 to 1). Fourteen days after treatment the serum albumin level was 3.94 Gm. and the globulin 3.07 Gm., a 1.3 to 1 ratio.

5. Changes noted in the blood and urine electrolytes will be reported elsewhere in detail. In general, it can be stated that the blood electrolyte values changed as would be expected.

Comment.—Symptomatically, this patient not only failed to respond to pituitary adrenocorticotropic hormone (100 mg. daily) but his ulcer was definitely aggravated during treatment. In addition, he had freckling pigmentation of the face and neck and a feeling of being "tired, restless, sleepy and exhausted." These symptoms completely disappeared 24 hours after hormone therapy was discontinued. The acute pain in the epigastrium also subsided, but moderate ulcer distress continued. The freckling pigmentation of the face and skin disappeared about two weeks after the hormone was discontinued.

As with our second patient who received cortisone, pituitary adrenocorticotropic therapy failed in the presence of a posterior wall duodenal ulcer which had previously penetrated (or perforated) the pancreas. Medical therapy had failed in both patients, and subtotal gastric resection was performed.

Case 4.—*History and Previous Course.*—Mr. L. B., aged 30, had an ulcer history dating from 1945. From 1945 to 1948, although he was receiving ambulatory ulcer management (frequent feedings and antacids) his symptom-free intervals were never longer than two to three months. Food and antacids gave him temporary relief. In November 1948 he was hospitalized at another institution and for a period of one week was given hourly feedings of milk and cream and an aluminum hydroxide preparation. There was a great deal of difficulty at first in obtaining symptomatic relief. The physicians in charge resorted to feedings of milk and cream and amphojel® every hour at night for several nights before the patient finally became free of distress. It was the opinion of the gastroenterologist that "medical management would not accomplish much for him either now or in the future," and gastric resection and vagotomy were advised.

Immediately after discharge of the patient from the hospital his distress recurred, and he continued to have symptoms day and night for four consecutive months. Four months after he left the hospital his distress became less acute but still persisted.

When we saw this patient June 29, 1949 he had acute pain in the epigastrium radiating to the left upper abdominal quadrant, left lower axilla and upper midback. The pain became severer about one hour after feedings and also at about 6:00 a. m. The patient was awakened by pain every one to two hours during the night, and food gave him relief for about one hour. There was no nauesa or vomiting.

Clinical and Laboratory Data.—Physical examination revealed essentially normal conditions except for tenderness in the epigastrium. Results of the usual gastrointestinal laboratory examinations were within normal limits. Roentgenologic study of the gastrointestinal tract showed "a prolonged and pronounced pylorospasm and spasm of the bulb. There was some tenderness and considerable deformity of the duodenal bulb. There was no definite crater. The five-hour study showed the stomach empty, with normal progress of the meal to the lower ileum." Hospitalization was refused. On an ulcer regimen with bed rest at home the patient became moderately improved but was not free from distress.

On May 1, 1950 acute pain developed in the epigastrium. Management at home failed to relieve the symptoms of the patient, who was hospitalized May 23, 1950. After five days the acute distress subsided somewhat. Cholecystography was normal. A repeat roentgenologic study of the gastrointestinal tract showed "thick and coarse mucosal folds chiefly in the prepyloric section. The duodenal bulb was found to be decidedly deformed, and there was extensive scarring from a chronic duodenal ulcer. There was no crater. Four hour gastric examination showed only a small residue of barium in the stomach. Most of the meal was in the ileum, and the motility was essentially normal."

It was our impression that the patient had a posterior wall duodenal ulcer which had penetrated (or perforated) the pancreas. A subtotal gastric resection was advised, but first we initiated hormone therapy. The laboratory examinations enumerated in case 3 were also done in this case.

Treatment and Course.—Because the symptoms in case 3 were aggravated during treatment, in case 4 we started treatment of the patient cautiously with smaller, more frequent doses 15 mg. of pituitary adrenocorticotropic hormone every six hours daily for the first four consecutive days (60 mg. a day); 20 mg. every six hours daily for the next four days (80 mg. a day); 25 mg. every six hours daily during the next two days (100 mg. a day), and 33.3 mg. every eight hours (three times daily) during the last six days of therapy (100 mg. a day)—a total of 1,360 mg. during 16 consecutive days.

On the fifth day of hormone therapy the patient's condition began to improve. He discontinued antacid therapy and did not require feedings between meals, although he was asked to continue with them. His appetite and general well-being also improved. He volunteered the information that "this is the best I have felt for months." He was definitely improved, although he had a gnawing sensation after being without food for three or four hours. On the twelfth day even this gnawing sensation disappeared. He became completely symptom free. However, several days after discharge from the hospital his ulcer distress recurred.

In this patient the eosinophil count during therapy failed to show the consistent drop noted in the preceding patient. The count fluctuated from day to day and at times even reached the pretreatment levels. It should be noted, however, that during the first eight days of therapy the hormone was administered in only 15 to 20 mg. doses. (A 50 per cent drop in eosinophils is expected four to eight hours after administration of a 25 mg. dose.) When the drug was administered in 25 and 33.3 mg. doses the eosinophil count dropped somewhat, but it did not fall below 50 per cent of the pretreatment level as was the case with the first patient treated with pituitary adrenocorticotropic hormone. However, four hours after the patient received a 33.3 mg. injection (Thorn test) the eosinophils dropped to below 50 per cent of the pretreatment count (from 143 to 31 eosinophils).

The urinary 11-oxycorticosteroids and 17-ketosteroids rose moderately but definitely, indicating a response of the adrenals to hormonal stimulation. Blood uric acid and acid phosphatase levels dropped moderately, but the blood electrolytes failed to show the degree of changes noted in case 3. These will be reported later in detail. Towards the end of hormone therapy the serum albumin-globulin also tended to assume a 1 : 1 ratio, as it had in case 3. After treatment with pituitary adrenocorticotropic hormone was discontinued the albumin-globulin ratio returned to normal.

The blood pressure remained at the pretreatment level. No side effects were noted except for a puffiness of the face during the last several days of hormone administration. The face became fuller, taking on the so-called buffalo-type obesity described by Cushing.

Comment.—In our opinion this patient has a posterior wall duodenal ulcer which had previously penetrated (or perforated) the pancreas. Pituitary adrenocorticotropic hormone was given initially in smaller doses (15 mg. every six hours, i. e., 60 mg. a day) and was well tolerated when the dosage was gradually increased to 100 mg. a day. When larger dosages were reached the patient became completely symptom free. However, several days after discharge from the hospital ulcer distress recurred.

SUMMARY

1. Mann-Williamson dogs treated with cortisone lived (on the average) at least twice as long as the untreated control animals. The animals treated with pituitary adrenocorticotropic hormone (ACTH) also lived longer than the untreated animals but not as long as the cortisone-treated animals. However, the beneficial effect of cortisone, and to a lesser degree of pitu-

itary adrenocorticotropic hormone, is not specific. Similar results were obtained in another concurrent series of Mann-Williamson dogs treated orally with an extract prepared from urine of pregnant mares (uroanthelone, kutrol®).

2. Patients with duodenal ulcer, studied to date, have shown a trend toward lower urinary excretion of 11-oxycorticosteroids during periods of ulcer distress. This was statistically significant when compared to the excretion of normal subjects and of the same ulcer patients during symptom-free periods. These preliminary findings are presented to stimulate additional comparative studies in larger series of ulcer patients. Similar studies are now in progress to determine whether patients with other chronic gastrointestinal diseases (gastric ulcer, ulcerative colitis or regional ileitis) show similar changes.

3. Four patients with long-standing chronic duodenal ulcers, intractable to the usual hospital management, were treated with either cortisone or pituitary adrenocorticotropic hormone:

(*a*) One of the two patients treated with 100 mg. of cortisone daily failed to respond to treatment. At surgical intervention a posterior wall duodenal ulcer was found that had penetrated deeply (or perforated) the pancreas. This complication no doubt existed before cortisone therapy was instituted.

The second patient, similarly treated, became symptom-free during cortisone therapy. Nine months later she said, "I am feeling better than at any time during the last ten years" (of her ulcer history).

(*b*) One of two patients treated with 100 mg. of pituitary adrenocorticotropic hormone daily had severer ulcer pain and definitely became worse during therapy. The symptoms and physical observations were those of impending perforation. Not only was there greater severity of ulcer pain but in addition the patient became "tired, restless and sleepy" and had a feeling of extreme "exhaustion." Freckling pigmentation of the face and mild hypertension also developed. Hormone treatment was discontinued, and within 24 hours the ulcer distress subsided and the general condition of the patient improved. At surgical intervention it was found that a posterior wall duodenal ulcer had penetrated (or perforated) the pancreas—a complication that had apparently existed before pituitary adrenocorticotropic therapy was begun.

The other patient was started on a smaller dosage of the hormone (60 mg. daily) which was increased gradually until 100 mg. a day was administered. He began to improve on the fifth day of treatment and became completely symptom free. When higher dosages were reached he tolerated the drug well. No other side effects were noted, except that his face became fuller and took on the so-called buffalo-type contour described by Cushing. This manifestation disappeared when hormone therapy was discontinued. However, several days after discharge of the patient from the hospital his ulcer distress returned, with pains not unlike those he experienced prior to pituitary adrenocorticotropic therapy.

4. For the present, a conservative medical regimen is still the treatment of choice for patients with duodenal ulcer. This regimen consists of rest, frequent small feedings of bland foods, antacids, antispasmodics, sedatives, gastric aspiration and lavage when indicated, and reassurance. When such a regimen fails, one might in addition give cortisone or pregnant mare's urine extract orally (uroanthelone, kutrol®) before resorting to surgical measures. The Mann-Williamson animals treated with these agents lived longer than the untreated animals and, as a group, were in a state of excellent nutrition and greater vigor. In ulcer patients, on the basis of experience to date, pituitary adrenocorticotropic hormone should be used guardedly if at all.

ADDENDUM

We are indebted to Dr. Seymour Gray of Peter Bent Brigham Hospital for the following case history of a woman in whom, as in our first patient treated with pituitary adrenocorticotropic hormone, there developed such severe epigastric pain (while she was receiving initial doses of 25 mg. four times a day, or 100 mg. daily) that the drug had to be discontinued because of definite danger of perforation and localized peritonitis:

History and Examination.—A woman aged 66 entered the hospital with a history of a gastric ulcer, diagnosed and treated for two months in another hospital. The patient apparently had had the ulcer for about five years. She presented the classic symptoms of epigastric pain occurring several hours after meals and relieved by ingestion of food. The patient was awakened occasionally at night by the pain. Roentgenograms revealed a gastric ulcer on the lesser curvature of the stomach. Gastroscopy confirmed the diagnosis. The gastric ulcer could be seen clearly on the lesser curvature of the anterior wall. The ulcer was approximately 1 inch (2.54 cm.) in diameter and approximately ⅜ inch (0.95 cm.) in depth. The impression was gained that this was a benign lesion.

Treatment and Course.—The patient was treated with a regimen of ulcer management consisting of milk and cream and a preparation of aluminum hydroxide gel with magnesium trisilicate (gelusil®) and had a prompt response. Her symptoms cleared and she felt quite well. The ulcer management was then discontinued, except for the ulcer diet and frequent feedings of milk and cream. The patient remained essentially asymptomatic.

Pituitary adrenocorticotropic hormone was then administered in doses of 25 mg. four times a day. Within twenty-four hours the patient began to complain of a recurrence of her ulcer pain. She had sharp, gnawing, upper abdominal pain which was decidedly aggravated during the night and was associated with much flatulence and lower abdominal distention. After three days of hormone administration there was pronounced epigastric tenderness and a localized area of protective muscle spasm which had hitherto not been present. The gnawing epigastric ulcer distress still persisted. After five days of hormone therapy there appeared to be definite evidence of peritoneal irritation, as manifested by an area of severe muscle spasm and exquisite localized tenderness in the epigastrium. The patient complained bitterly of pain, which doubled her up on occasions. She felt that the pain was partly relieved when she drew up her legs.

On the sixth day of hormone administration it was believed that there was definite danger of perforation and localized peritonitis. The white blood cell count[12] had risen from 8,500 to 15,000 and the stools became guaiac positive, although there was no significant fall in the hematocrit. The patient consequently was placed on a regular regimen of milk, cream and aluminum hydroxide gel with magnesium trisilicate. This gave her partial relief, but she still complained of definite ulcer pain, particularly severe at night. The pain, tenderness and physical observations that suggested a localized peritoneal reaction remained unchanged. After ten days of administration of 100 mg. of the hormone a day, all medication was stopped. The roentgenograms revealed no change in the size of the ulcer, and there was no evidence of healing gastroscopically.

The patient was then given frequent feedings of milk and cream and Sippy powders. Within a few hours all her pain disappeared and she became essentially asymptomatic. Within 48 hours the localizing signs in the epigastric area had disappeared and the patient was quite comfortable. After several weeks a gastric resection was performed and the ulcer in the stomach was found to be perfectly benign.

---

[12] In both of our patients treated with pituitary adrenocorticotropic hormone and in one of the two cortisone-treated patients (case 1, Miss V. E.) leukocytosis developed during therapy (D.J.S.).

ENERGY EXPENDED BY PATIENTS ON THE BEDPAN AND BEDSIDE COMMODE

JOSEPH G. BENTON, Ph D, M D.
HENRY BROWN, M D.
and
HOWARD A RUSK, M D.
With the Technical Assistance of Joan Birnbaum, M.S.
New York

"I didn't mind the operation or anything at all about the hospital except the bedpan," is one of the commonest expressions heard from discharged patients. The bedpan as an important adjunct in the management of the bed patient had probably been used for many years previous to the issuance[1] of the American patent in 1877. It is apparent that its use was widespread at the time since it was mentioned in nursing manuals[2] and advertised in catalogs of surgical and hospital supply companies. Defecation on the bedpan is difficult and sometimes dangerous, and in addition to the psychological indignity imposed on the patient it subjects him to physiological discomfort and stress. Despite this, it has been universally used[3] partly through habit and partly because with certain types of cases it is obviously a necessity.

Fortunately there has been a recent tendency to advocate more extensive use of the bedside commode,[4] since it has been assumed that this imposes less strain on the patient in terms of energy expenditure. This situation notwithstanding, the physician who recommends the use of the commode is often considered radical, and the occasional death of a patient while using the conventional bedpan still is construed as an inevitable "act of Providence."

Despite the impression that the use of the bedpan imposes a greater strain on the cardiovascular and respiratory systems than does the use of the commode, there have been no objective studies which would indicate that it subjects the normal as well as the diseased person to an unfavorable stress or greater energy expenditure. Thomas and Harrison[5] in discussing the relationship of decrease in metabolism and bedrest, stated that "data are needed concerning the relation of defecation to this problem. The respective metabolic increments induced by using a bed pan and a bedside commode should be investigated."

Because of this and because there is evidence that prolonged bed rest is harmful and that the practice of early ambulation is beneficial in a wide variety of clinical states,[6] the present study was undertaken as one phase of a broader exploration to determine the energy cost of activities of daily living and selected occupational activities in normal persons as well as in patients with disease that requires their prolonged confinement to bed.

METHODS

The facility of measurement of oxygen consumption with the closed circuit metabolism apparatus during activity[7] and the use of such data as a measure of the energy cost of activity have already been established.[8] These methods using a 9 liter respirometer of the Benedict-Roth type have been adapted to the present study because they are simple and also the most universally applicable.

Patients were selected from the wards of the Fourth (New York University) Medical Division and the Physical Medicine and Rehabilitation Service of Bellevue Hospital. A total of 28 subjects was studied; 15 were cardiac patients and the remainder either normal or with other diseases as indicated in table 1. Some of the normal subjects were hospital personnel. At the time of study all the cardiac patients were compensated and on an adequate maintenance regimen. An attempt was made to match subjects in each group with regard to ranges of age, sex, weight and height. Diagnoses and other data pertaining to the subjects are listed in tables 1 and 2. These persons were all ambulant or semiambulant and had been required, on a physician's orders, to use the bedpan during a past or the current hospital admission. No subject was included in the series who presented evidence of musculoskeletal disability, thyroid disease or blood dyscrasia.

Early in the investigation it became apparent that there were serious obstacles to the study of patients during actual defecation. Not the least of these were psychogenic and temporal factors. It was therefore decided to have the subjects simulate the process as closely as possible by means of "bearing down" or performing Valsalva maneuvers, on both the bedpan and

TABLE 1—*Occupation, Age, Sex and Diagnosis of Fifteen Cardiac and Thirteen Noncardiac Subjects*

Subject	Age	Sex	Occupation	Diagnosis * at Present Hospitalization
Group 1, Cardiacs				
A S	50	M	Tailor	Arteriosclerotic heart disease, enlarged heart, coronary sclerosis, myocardial fibrosis, old anterior wall myocardial infarct, acute posterior wall infarct, regular sinus rhythm, congestive heart failure, class IV E to III D
R S	47	M	Merchant mariner	Arteriosclerotic and hypertensive heart disease, enlarged heart, coronary sclerosis, myocardial fibrosis, acute anterior wall myocardial infarct, regular sinus rhythm, anginal syndrome, congestive heart failure, class IV E to III D
W M	49	M	Unemployed	Rheumatic heart disease, enlarged heart, mitral insufficiency, mitral stenosis, auricular fibrillation, acute pulmonary edema, class IV E to III C, hypertension, etiology?
A P	43	M	Bartender	Heart disease, etiology unknown (arteriosclerotic? syphilitic? hypertensive?), enlarged left ventricle, dilated aneurysmal aorta, aortic stenosis, aortic insufficiency, regular sinus rhythm, left bundle branch block, first degree auriculoventricular block, acute left ventricular failure, class IV E to II B, syphilis, late latent, treated
D E	51	M	Unemployed	Rheumatic heart disease, enlarged heart, mitral insufficiency, mitral stenosis, aortic insufficiency, aortic stenosis, auricular fibrillation, class III C, diabetes mellitus, mild
J B	33	M	Restaurant worker	Rheumatic heart disease, enlarged heart, mitral insufficiency, mitral stenosis, aortic insufficiency,? aortic stenosis, regular sinus tachycardia, class II D, subacute bacterial endocarditis, active, under treatment
L R	59	M	Unemployed	Hypertensive heart disease, slightly enlarged heart, regular sinus rhythm, class I A, status postoperative for gastroenterostomy, secondary to peptic ulcer, colitis, chronic, mild, renal calculus, staghorn type, right kidney
M P	65	F	Housewife	Heart disease, etiology unknown, enlarged left ventricle, enlarged right ventricle, enlarged left auricle, auricular fibrillation, class III C
W B	64	M	Electrician	Arteriosclerotic and hypertensive heart disease, enlarged heart, coronary sclerosis, myocardial fibrosis, valvular sclerosis, regular sinus rhythm, occasional auricular and ventricular premature contractions, class I B
F W	56	M	Cook	Arteriosclerotic heart disease, coronary sclerosis, myocardial fibrosis, acute myocardial infarct, regular sinus rhythm, class IV E to III C
A G	53	M	Unemployed	Arteriosclerotic and hypertensive heart disease, enlarged heart, coronary sclerosis, myocardial fibrosis, paroxysmal ventricular tachycardia, first degree auriculoventricular block, left bundle branch block, coronary insufficiency, class III C
S R	63	M	Unemployed	Arteriosclerotic and hypertensive heart disease, enlarged heart, dilated aorta, calcific aortic stenosis, coronary sclerosis, myocardial fibrosis, aortic insufficiency, acute left ventricular failure with pulmonary edema, class IV E to III C
M G	44	F	Housewife	Rheumatic heart disease, enlarged heart, mitral insufficiency, mitral stenosis, regular sinus rhythm, class II B
C C	65	M	Unemployed	Arteriosclerotic and hypertensive heart disease, enlarged heart, coronary sclerosis, myocardial fibrosis, congestive heart failure, right hydrothorax, class IV E to III C
Y B	62	M	Barber (unemployed)	Arteriosclerotic and hypertensive heart disease, enlarged heart, coronary sclerosis, myocardial fibrosis, sinus tachycardia, left ventricular failure, class IV E to III C, chronic bronchitis, chronic pulmonary fibrosis and emphysema
Group 2, Noncardiacs				
H B	31	M	Physician	No disease
R T	25	M	Laborer	Syphilis, late latent, untreated
E G	61	M	Unemployed	Laennec's cirrhosis with jaundice and edema
C W	47	M	Unemployed hospital attendant	Acute alcoholism, gastritis, acute, exogenous
F D	50	M	Printer	Rheumatoid arthritis, acute, active
C P	32	M	Electrician	Glomerulonephritis, acute, diffuse
W W	25	M	Unemployed actor	Diabetes mellitus
D D	20	F	Machine operator	Glomerulonephritis, acute, diffuse
K B	35	M	Physician	No disease
W N	34	M	Cab driver	Duodenal ulcer, active
L J	63	M	Unemployed	Hemochromatosis
F G	43	M	Physician	No disease
T R	36	M	Physician	No disease

---

* The cardiac diagnoses are given according to the nomenclature recommended by the New York Heart Association in their publication "Nomenclature and Criteria for Diagnosis of Disease of the Heart," New York, 1940. The classification by Roman numerals and capital letters refers to the functional capacity and therapeutic classification, respectively.

Functional Capacity

Class I—Patients with a cardiac disorder without limitation of physical activity. Ordinary physical activity causes no discomfort.
Class II—Patients with a cardiac disorder with slight to moderate limitation of physical activity. Ordinary physical activity causes discomfort.
Class III—Patients with a cardiac disorder with moderate to great limitation of physical activity. Less than ordinary physical activity causes discomfort.
Class IV—Patients with a cardiac disorder unable to carry on any physical activity without discomfort.

Therapeutic Classification

Class A—Patients with a cardiac disorder whose ordinary physical activity needs no restriction.
Class B—Patients with a cardiac disorder whose ordinary physical activity needs no restriction but who should be advised against unusually severe or competitive efforts.
Class C—Patients with a cardiac disorder whose ordinary physical activity should be moderately restricted, and whose more strenuous habitual efforts should be discontinued.
Class D—Patients with a cardiac disorder whose ordinary physical activity should be markedly restricted.
Class F—Patients with a cardiac disorder who should be at complete rest or confined to bed.

the commode for at least two trials of each. The procedures were fully explained and demonstrated to each subject. Uncooperative patients and those who had difficulty in understanding what was required were excluded from the study.

The tests were conducted in a small, quiet room away from the ward, using a low hospital bed with an innerspring mattress at a height of 22 inches (56 cm.) from the floor. A conventional metal bedpan was utilized. The bedside commode used was at approximately bed height (i. e., the height of the seat was 18 inches [46 cm.] from the floor) and was constructed with a conventional toilet seat and a back with two arm rests for support of the patient. The bed as well as the commode were enclosed by ward screens, permitting privacy for the subject. The observer sat outside the screens noting the record of respiration on the recording drum of the respirometer. Frequent observations were discreetly made through a small opening in the screen to assure the performance of the various maneuvers in the prescribed manner.

Table 2.—*Summary of the Mean Values and Ranges for the Age, Weight, Height, Body Surface Area and Resting Metabolism of Fifteen Cardiac Subjects and Thirteen Noncardiac Subjects*

	Age, Yr.	Weight, Lb	Height, In.	Body Surface Area, Sq. M.	Resting Metabolism,* Ml. O_2/Min
15 Cardiacs (13 males, 2 females)					
Mean	53.6	148	64.0	1.72	267
Range	33-65	127-172	61.0-69.5	1.60-1.82	223-334
13 Noncardiacs (12 males, 1 female)					
Mean	38.6	156	66.75	1.81	251
Range	20-63	112-200	62.25-71.5	1.49-2.08	177-321
All subjects					
Mean	46.7	152	65.2	1.76	260
Range	20-65	112-200	61.0-71.5	1.49-2.08	177-334

* Determined with the patient at rest in the supine position and corrected to standard conditions of temperature and pressure.

The tests were performed in all instances approximately two hours after meals. At each session both a bedpan and a commode experiment were carried out as described below. A 15 to 20 minute rest period was allowed between the two procedures, and on successive days the order of the maneuvers was alternated. The sequence of experiments was such that each subject served as his own control for purposes of comparing the two activities.

During the tests, male patients were attired in pajamas and females in hospital gowns. In order to allow free movement of the patient, the connection between the mouthpiece and the respirometer was made with 10 foot (205 cm.) lengths of flexible rubber tubing. Conventional rubber mouthpieces and noseclips were used, and the patient held the metal three way valve with one hand to avoid displacement of the mouthpiece when changing position.

The subjects rested in bed for 15 minutes prior to the actual experiment. The noseclip was adjusted and checked for leaks; the mouthpiece was placed in position, and recording of oxygen consumption was begun while the subject was in the supine position. Resting oxygen consumption was recorded for a period of four to six minutes. When it was apparent that an equilibrium had been attained, a signal was given by the observer for the patient to begin one of the following two activities, during which time oxygen consumption was continuously recorded:

1. The patient (if a male) untied or unbuttoned his pajama pants, sat up, turned, slid off the bed and sat down on the commode seat adjacent to the bed. He remained seated and performed 10 Valsalva maneuvers which simulated straining at stool. He then cleansed himself with toilet tissue and at a second signal from the observer pulled up his trousers and returned to bed, again assuming the supine position. The time between the two signals was three minutes

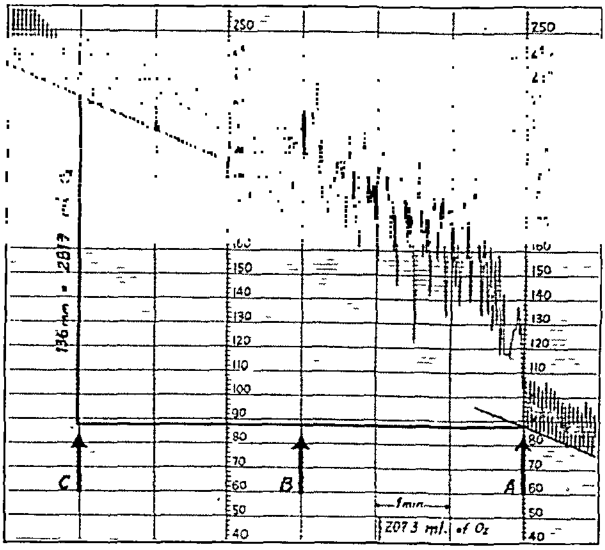

Fig. 1.—Photograph of a portion of the respirometer record showing oxygen consumption in cardiac subject A. P. while performing 10 Valsalva maneuvers (indicated by small arrows) on the bedpan. *A* indicates the start of the activity; *B*, the end of the activity and beginning of recovery, and *C*, the end of the three minute period of recovery.

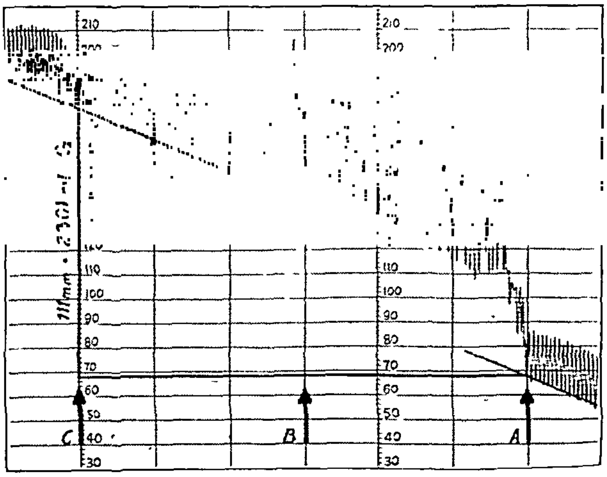

Fig. 2.—Same as figure 1, but with the cardiac subject, A. P., on the bedside commode. Note that oxygen consumption of the patient is 518 milliliters (uncorrected) greater on the bedpan (fig. 1) than on the commode.

2. The patient untied his pajama pants, drew them down, mounted the bedpan (which had been placed on the bed before the start of the test) and sat on it in the center of the bed. This position was selected since observations made on various services of this hospital indicated that this was the common practice. He was permitted to mount the bedpan in any manner he found easiest. While in this position, he performed

10 Valsalva maneuvers He then cleansed himself with toilet tissue and at a second signal, three minutes after the first, resumed the supine position in bed and pushed the bedpan aside

In all instances the recording of oxygen consumption of the patient in the supine position was continued for a four to six minute period after completion of the activity in order to determine the "recovery" oxygen consumption. It was found that the rate of oxygen consumption during the recovery period reached a steady state usually within one minute and always within three minutes. This recovery rate was almost identical with the preactivity resting rate

* In milliliters of oxygen at standard conditions of temperature and pressure in excess of the resting oxygen consumption for the six minute test period, which includes three minutes of activity and three minutes of recovery

Data were calculated from the graphic records (figs. 1 and 2). Energy cost of each of the maneuvers was determined in the following manner: The oxygen consumption during the three minutes of bedpan or commode activity and three minutes of recovery was measured from the graphic record. From this was subtracted the resting oxygen consumption for a six minute period This resulted in a figure for excess oxygen consumption for the six minutes activity and recovery period which was the energy cost of the particular maneuver under study. All gas values are corrected to standard conditions of temperature and pressure and expressed as milliliters of oxygen in excess of the resting oxygen consumption.

RESULTS

Early in the course of the study it became apparent that in all patients of the noncardiac as well as the cardiac group there was a consistently greater oxygen consumption for the performance of the outlined procedures on the bedpan than on the commode (table 3). It was also noted that there was no consistent effect of accommodation on serial performance, some subjects using more while others consumed less oxygen at successive trials There frequently was considerable variation at succeeding trials in the same person. Furthermore, the two groups of subjects showed no significant difference in oxygen consumption with regard to the two respective maneuvers. This was anticipated, since the amount of work done in either activity was not great enough to incur a significant oxygen debt. On this basis the data for the entire series, including both cardiac and noncardiac subjects, were combined and statistically analyzed (table 4).

When the differences of the means in oxygen consumption of the entire series of subjects in the two categories of activity were analyzed, a statistically highly significant *p* value (< 0.001) was found.[9] There was a mean of 50.7 per cent greater increment of oxygen consumption above resting levels in the cardiac group while using the bedpan and a mean of 48.4 per cent for the noncardiac group.

TABLE 4—*Statistical Analysis of the Data Comparing the Mean Excess Oxygen Consumption for the Use of a Bedpan and a Bedside Commode in Twenty-Eight Subjects*

Subjects	No	Mean Difference (B — C) Ml O	Standard Error of Mean Difference	t = Mean Difference / Standard Error	*p* Value*
Cardiac	15	+ 337	64.82	5.2	<0.001
Noncardiac	13	+ 312	56.51	5.5	<0.001
All subjects	28	+ 325	42.80	7.6	<0.001

Percentage mean excess oxygen consumption for use of bedpan over commode in

(1) 15 cardiac subjects $\frac{337 \times 100}{665} = 50.7\%$

(2) 13 noncardiac subjects $\frac{312 \times 100}{646} = 48.4\%$

* Computed according to Fisher and Yates [9]

Blood pressure, pulse rate and electrocardiographic tracings taken before, during and after the two activities were subject to many extrinsic physical and emotional factors and resulted in extremely variable data. For these reasons it was deemed not feasible to study these routinely, especially since a cardiodynamic study of patients while performing Valsalva maneuvers has been reported by McGuire and others.[10] These workers found that during such straining there occurred decided changes in rate and rhythm of the heart, accompanied with sharp rises in intra-arterial and intrapleural pressures; they concluded that cardiac arrhythmias, vascular hemorrhage or pulmonary embolism were the mechanisms responsible for death of subjects while straining at stool

COMMENT

While it is obvious to both the user and the observer that the use of the bedpan causes psychological trauma, irritation and often resentment, the results of this study indicate that it is an unphysiological procedure from the standpoint of energy cost. It would seem that the supported sitting or squatting position is the optimum posture for defecation. This is a truism which carries over from studies of primitive obstetric customs in which the squatting position was the postural choice for parturition. The conventional use of the bed pan in bed precludes the assumption of the customary posture of choice in defecation and hence makes this method undesirable. The commode, on the other hand, allows for the assumption of a supported, familiar posture and, aside from the subjective feelings of the patient, imposes on him less physiological stress.

---

[9] Fisher, R A, and Yates F Statistical Tables for Biological Agricultural and Medical Research, New York, Hafner Publishing Company, 1948

[10] McGuire, J, and others Bed Pan Deaths, Am Pract 1:23, 1950 Contribution a l'Étude de la ranimation dans les états de mort apparente

It is recognized that a sudden severe straining or movement on either the bedpan or the commode can cause precipitous changes in blood pressure or decided rises in intrapleural and abdominal pressures which might induce serious cardiovascular accidents, but from both a postural and energy-conserving standpoint the strain necessary for defecation is lessened by the use of the commode or stool. Moreover, it is also recognized that for patients who are unconscious, disoriented, decidedly debilated or afflicted with severe physical disabilities, the use of the bedpan is a matter of practical necessity.

In a small series of three patients the use of the bedpan with the legs swung over the side of the bed and feet resting on a small stool resulted in less oxygen consumption than the use of the bedpan in the sitting position in bed. In this connection, the posture of the severely ill or debilitated patient for whom use of the commode is not feasible may be altered by use of pillows and adjustment of the bed to conform somewhat to the supported position, and in such instances this may be of decided benefit.

From postural considerations it might be assumed that had the supine position been used with the bedpan, the difference in energy cost would have been even greater between subjects on the bedpan and those on the bedside commode.

SUMMARY AND CONCLUSIONS

1. Oxygen consumption (in excess of resting) was determined by means of a closed circuit respirometer in a group of 13 noncardiac and a group of 15 compensated ambulant cardiac subjects while performing Valsalva maneuvers on the bedpan and on the bedside commode under standardized conditions.
2. There was no significant difference for each of the respective activities in the noncardiac and cardiac groups, but energy expenditure in terms of oxygen consumption above resting levels was consistently higher on the bedpan than on the commode (50.7 per cent for the cardiac group and 48.4 per cent for the noncardiac).
3. The difference in mean excess oxygen consumption for the use of a bedpan and a commode in all subjects was objectively and statistically highly significant.

Malignant Tumors of Bone.—Bone sarcoma has one main difference from other malignant lesions in that it most often affects relatively young persons. Its highest point of incidence is among persons of 15 to 20 years of age, according to statistics compiled by Christensen. Plans for cancer detection, therefore, must include this age group, if persons suffering from malignant tumors of bone are to benefit under any mass tumor detection program. Mayo Clinic statistics, recently compiled by Meyerding and Jackson, show that in 75 per cent of cases osteogenic sarcoma occurs about the knee. This localization to the lower end of the femur and the upper end of the tibia and fibula in three fourths of all cases of osteogenic sarcoma is extremely significant. It proves, in my opinion, that trauma, occurring as it does so frequently about the knee, is a definite inciting factor in the production of certain malignant bone tumors.—Mark B. Coventry, M.D., Differential Diagnosis of Malignant Bone Tumors, *Annals of Surgery,* November 1950.

Special Article

MANUAL ARTIFICIAL RESPIRATION

Comparison of Effectiveness of Various Methods on Apneic Normal Adults

ARCHER S. GORDON, M.D.
FRANK RAYMON, B.S.
MAX SADOVE, M.D.
and
A. C. IVY, M.D.
Chicago

In the final analysis, the critical evaluation of manual methods of artificial respiration requires documented field tests,[1] so that the practicality and adequacy of the various technics may be determined. However, the practical utilization of any manual resuscitation procedure must stem from results obtained under ideal or controlled experimental conditions, because of the *numerous uncontrolled factors incident to field testing.*

Anatomic considerations preclude the use of animals for this work. However, three types of human subjects can be utilized: (*a*) nonrigid corpses, immediately after death and before the onset of postmortem rigor, (*b*) conscious, normal subjects, trained to "voluntarily suspend respiration," or hyperventilate to the point of apnea, and (*c*) normal subjects rendered apneic by curare (or a curare-like preparation) and/or anesthetic agents. Patients rendered apneic by central nervous system pathology, such as anterior poliomyelitis, are inadequate, in our experience,[1] for the unequivocal evaluation of all manual maneuvers.

In a previous study[2] we compared the effectiveness of the various manual methods for artificial respiration by first using warm corpses and then subjects trained to suspend their respiration voluntarily. In the present study we have again compared the effectiveness of these methods on subjects with voluntary suspension of respiration and the same subjects when they were made apneic by curare-anesthesia agents.

METHODS

Eleven normal, healthy, adult males, ranging in age from 22 to 31 years and weighing 130 to 205 pounds (59 to 93 Kg.) were used. The history and physical examination of each showed freedom from cardiorespiratory pathology, a normal electrocardiogram and an essentially normal chest roentgenogram. The normal resting tidal air was determined, and, after proper indoctrination, the pulmonary ventilation effected by nine manual methods of artificial respiration was measured while the subject passively suspended respiration. All measurements were made on a standard basal metabolic rate spirometer (Sanborn waterless) via a rubber mouthpiece and with the usual nasal clip in place. Thereafter, each subject was premedicated with an adequate dose of atropine sulfate (0.60 or 1.20 mg.) either intravenously or intramuscularly, depending on the interval before anesthesia was begun. Then each subject was given a mixture containing 500 mg. of thiopental sodium and 6 cc. of standard *d*-tubocurarine chloride (a total of 120 units, or 18 mg. of the hydrated

salt) in a total of 21 cc. of solution. Injection of the solution into one of the cubital veins required only 30 to 60 seconds. This depressed respiration to apnea, or near-apnea, and artificial respiration was then started via the breathing bag of the anesthesia machine, with the use of a cyclopropane-oxygen mixture. If respiration was not assisted and cyclopropane added, one could detect the diaphragm weakly attempting to initiate respiration. When the subject was completely apneic, a cuffed endotracheal tube was inserted into the trachea, with laryngoscopic visualization. There was no "bucking" of the subject in response to passage of the tube. No complications with reflexes or intubation occurred. The cuff that surrounded the tube was inflated with air to make the system gas tight.

The cyclopropane-oxygen mixture was again administered until complete relaxation and total apnea were attained. When the subject was in this state, the slightest pressure on the anesthesia bag created an exchange. The subjects were all examined for mechanical difficulties (such as endobronchial intubation). Each method of artificial respiration was then executed at a rate of 12 times per minute for periods exceeding one-half minute each. Between each method the subject was ventilated with the anesthetic mixture to insure complete apnea and freedom from any muscular activity. This state was reached and maintained during the measurement of each maneuver. In no case was any muscular activity or spontaneous respiratory movement noted on either the graphs or the subjects during a test run. Pulmonary ventilation was again measured on a standard basal metabolic rate spirometer filled with oxygen; the spirometer was calibrated by displacement of varying known amounts of air into the apparatus. This was adapted directly to the endotracheal tube. A flutter valve was interposed between the subject and the spirometer, providing separate inspiratory and expiratory circuits, thus reducing the size of the dead air space. A soda lime cannister, provided in the spirometer, prevented accumulation of carbon dioxide.

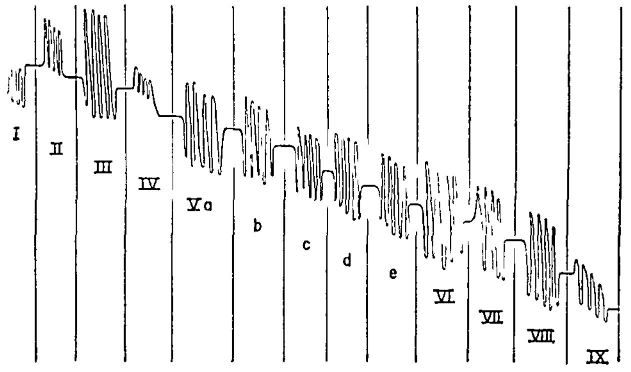

Fig 1.—Sections of graphic results obtained on one subject (R P) with the basal metabolic rate spirometer with various methods of manual artificial respiration I, Schafer (prone pressure), II, Emerson, (hip lift); III, Schafer Emerson Ivy (hip lift prone pressure), IV, Emerson (hip roll); V, Schafer-Emerson Ivy (hip roll prone pressure) as accomplished by five different operators (*a*, *b*, *c*, *d* and *e*), VI, Silvester; VII, Drinker modification of Nielsen (arm lift prone pressure), VIII, Nielsen (arm lift scapular pressure), and IX, Eve (rocking)

At the conclusion of the experiment the subjects were given nitrous oxide-oxygen mixtures (80:20) until muscular activity was such as to indicate that there would be an adequacy of exchange without the endotracheal tube. This state was usually reached in about 35 minutes. In one case the tube was removed in approximately 40 minutes and the subject was unable to maintain his airway. After reintubation, nitrous oxide-oxygen mixtures were administered for an additional half-hour.

The only sequela noted was a sore throat of varying degree in several of the candidates. All walked out of the operating room within 2.5 hours after the initial curare–thiopental sodium injection. These comments regarding our fortuitous experiences in this work should not be misconstrued as statements of the simplicity and safety of the method. Our cognizance of the many hazards and possible complications was of inestimable value in the prevention of such eventualities However, it must be emphasized that competence in anesthesiology and an accurately perfected experimental technic are prerequisites for such an undertaking.

METHODS OF ARTIFICIAL RESPIRATION STUDIED

The manual methods of resuscitation compared were those that are generally used or advocated today. Every method was applied to every subject during both the passive suspension phase and the curarization phase by the same operator (A. S. G.) except the Drinker modification of the Nielson method, which requires two operators. In this case, the assistant was always the same (F. R.). In this way, we hoped to obviate any variability that might have been introduced by using several persons, who may have performed the procedures in different manners.

The Eve rocking method[3] of activation of the inert diaphragm was included because (*a*) it was easily adapted to our procedure here, (*b*) it was previously included in our study on nonrigid corpses[2] and (*c*) it is commonly suggested for lay use as a "manual" method. Strictly speaking, however, the Eve method, or any method that necessitates the use of equipment—either provided or improvised—must always be considered a mechanical method. Nevertheless, the Eve tilt table was included in the study, despite the fact that it is not a manual method per se.

The manual methods performed were (*a*) Schafer (prone pressure),[4] Emerson (hip lift),[5] Emerson (hip roll),[2] Silvester,[6] Nielsen (arm lift-scapular pressure),[7]

Drinker, modification of Nielsen (arm lift-prone pressure),[8] Schafer-Emerson-Ivy (hip lift-prone pressure)[9] and Schafer-Emerson-Ivy (hip roll-prone pressure).[2] These methods have all been described and illustrated in a previous communication (*fig. 1 in* Gordon, Fainer and Ivy [2]).

RESULTS

Mechanical and anesthesia difficulties encountered in perfecting the technic invalidated the results obtained on the first subject. Thereafter, perfect relaxation and total apnea were secured, as indicated, in the remaining 10 subjects, and valid graphic tracings were shown by the method previously described (fig. 1).

On the basis of pulmonary exchange secured, the various methods can be divided into major groups. Those utilizing a "push and pull" maneuver produce active inspiration and active expiration, and, in those utilizing a "push" or a "pull" maneuver alone, only one half of the cycle is active and the other half is passive.[2]

The results obtained with passive suspension of respiration (table 1) and total apnea under curare-anesthesia (table 2) were completely corroboratory, although the former method achieved approximately 1.5 times as much pulmonary ventilation as the latter method. Table 3 reveals that all the methods in the "push" or "pull" group gave values approximating the normal resting tidal air in all 10 subjects, whereas the "push and pull" methods were approximately twice as efficacious. The "push and pull" manual methods include the Nielsen (arm lift-scapular pressure), Drinker modification of Nielsen (arm lift-prone pressure), Silvester method, hip lift-prone pressure and hip roll-prone pressure methods and effect approximately twice as much pulmonary ventilation as the prone pressure, hip lift or hip roll methods, which are "push" or "pull" manual methods. The Eve rocking method, a mechanical technic, yielded values intermediate between these two groups.

Certain correlations were noted between the body types of the subjects and the amount of pulmonary exchange elicited by the various methods of artificial respiration (fig. 2). Although in all apneic subjects the "push and pull" methods are superior to "push" or "pull" methods alone, the comparative values are not consistent in subjects of various body types. The values with the "push and pull" methods are disproportionately higher in tall persons than in those of medium or short stature. The Eve method maintains a relatively constant intermediate position, except that in the short stocky body type (only one case) it is as good as any manual method except the hip lift-prone pressure method. The results of hip lift-prone pressure method were consistently highest in all body types except in the tall, thin subject, in whom it was exceeded only by the Silvester method.

COMMENT

Previous evaluations of the efficacy of various manual methods for artificial respiration by other workers have been relatively inconclusive. This is because they (*a*) fail to consider all practical or generally advocated methods, (*b*) use only a few cases and/or (*c*) fail to evaluate pulmonary ventilation, per se, by providing controlled conditions, such as patency of the airway. However, in these studies for the first time the same group of investigators have appraised all the practical manual methods of resuscitation (as well as the Eve rocking method) under ideal, controlled, experimental conditions, for all three types of human subjects.

Pulmonary ventilation on (*a*) warm corpses, (*b*) normal healthy trained adults with passive suspension of respiration and (*c*) the same adults rendered totally apneic with curare-anesthesia are completely corroboratory. All results confirm the observation that, regardless of the type of subject, a "push and pull" maneuver is approximately twice as efficacious as a "push" or a "pull" method alone. The only difference noted is that the totally apneic subjects yield average values that are two times those of the warm corpses, whereas the results with passively suspended respiration are three times those obtained on the corpses (table 3).

Observations on these three types of human subjects have been questioned by some, with respect to their applicability to victims requiring resuscitation. Doubts are raised because of (*a*) early postmortem changes and absence of muscle tone and reflexes in corpses, (*b*) absolute muscular atony in curarized subjects and (*c*) the action of protective reflexes, as well as the difficulty in sustaining a state of passive suspension of respiration in conscious normal subjects. However, these studies indicate that the comparative values with any or all of these three types of subjects reveal the same effectiveness of pulmonary ventilation. It is essential that the corpses be used immediately after death, the curarized-anesthetized subjects be totally apneic and the passive normal subjects be trained adults.

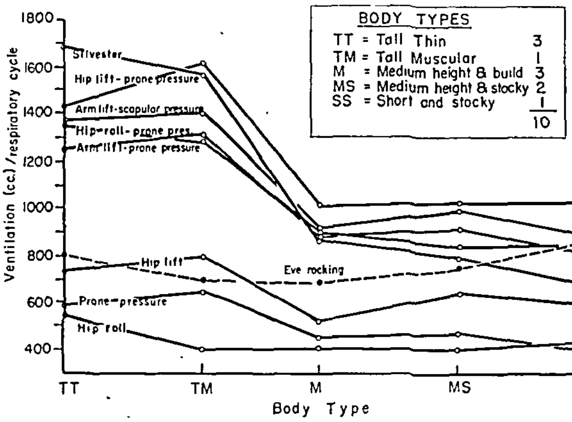

Fig. 2.—Efficacy of the various methods of artificial respiration with respect to specific body types in series of 10 totally apneic, normal, male adults.

The absolute values in any type of subject are not as important as the comparative values with the various manual methods—as long as the method in question results in adequate pulmonary ventilation. The actual values for pulmonary ventilation attained in victims requiring resuscitation probably are to be found between our values for the corpses and those for the totally apneic normal subjects. Those subjects that are most resuscitable probably simulate our totally apneic subjects, whereas victims that are at the limits of resuscitability are more apt to resemble the corpses. The values for the "push and pull" methods in the apneic subjects may, at first, appear excessive. However, these are actually a form of forced inspiration and forced expiration and should be significantly greater than the normal resting tidal air.

Despite the complete muscular atony of the apneic subject, respiratory graphs reveal that, even in the passive inspiratory phase of Schafer prone pressure, the thorax returns to its previous base level (fig 1) This "restitution" recoil is primarily dependent on the structural design of the thoracic cage and its attachments On the other hand, it was noted in the corpses[2] that restitution almost returned the chest to its resting base level (fig 1 in Gordon, Fainer and Ivy[2]) Fixed, emphysematous, senile or deformed chests might fail to respond in this normal manner The smaller values attained with warm corpses are probably due to total absence of reflex activity and a nonfunctioning circulatory system, whereas the greater values in normal passive subjects reflect the inability to completely suppress normal respiratory mechanisms and the desire to breathe

Pask[10] concurs in that "there seems little doubt that the conscious subject is quite unsatisfactory for this type of experiment, as true passivity of the respiratory mechanism is unattainable." He studied two intubated subjects anesthetized with a thiopental sodium-ether combination and rendered apneic by forced ether inhalation.[11] In these subjects, he found that the Eve rocking method gave greater pulmonary ventilation than the Silvester, Schafer or hip lift methods. His values are comparable to those obtained in our study, with the exception of the Silvester Method. However, in referring to specific body types, it is observed that the short stocky subject in our results gives comparable values to those in these two cases.

---

[10] Pask, E A The Efficiency of Methods of Artificial Respiration, Medical Research Council, Royal Naval Personnel Research Committee London, His Majesty's Stationery Office 1946

The use of only two cases and the failure to use several of the "push and pull" methods make Pask's results inconclusive in the evaluation of manual artificial respiration and the Eve method. This is especially true in view of our observation that certain body types may give more favorable results with certain methods (fig. 2). Pask infers from oxygen consumption results "that Eve's rocking method may assist blood circulation." However, we do not feel that oxygen consumption alone is a true measure of the circulatory effects of manual artificial respiration or the Eve method. In the determination of the effect of artificial respiration on circulation, any method that depends on oxygen saturation must consider variable amounts of oxygen provided by the different methods. A purely physical method of measuring blood flow, or possibly the direct Fick principle, would be most desirable. However, measurements of blood flow were not included in our work because we were primarily concerned with pulmonary ventilation and could not justify the use of a more involved procedure in our subjects for this determination.

One of the major factors promoting the return of venous blood to the heart is the "sucking" action created by the negative intrathoracic pressure during inspiration. Therefore, any method creating such a condition should augment a failing circulation. All the "push and pull" technics accomplish this. The hip lift-prone pressure and hip roll-prone pressure should be additionally efficacious, since the body is in a head-down position during the inspiratory (sucking) phase and blood may tend to drain toward the heart.

Even in this comparatively small series (10 cases), there is a tendency to correlation between specific body types and the efficacy of pulmonary ventilation with certain manual maneuvers (table 2 and fig. 2).

The hip lift-prone pressure method was universally the most effective, except in the tall thin subject, in whom it was exceeded by the Silvester method (three cases). But the Silvester method was the poorest form of "push and pull" ventilation in the medium and short subjects. In fact, in the short stocky subject (one case) it was even exceeded by the Eve rocking method. However, this series is large enough only to permit inferences on this observation, and a much larger group would be necessary for statistically significant data. Figure 2 reveals the sharp delineation of the various methods into two groups—a "push and pull" and a "push" or "pull" alone, with the Eve rocking method intermediate.

The hip roll-prone pressure method and the Nielsen method (arm lift-scapular pressure) were tried by five operators on one subject so that the variability that might result from more or less instruction and training (fig. 1) might be appraised. Although the differences were not particularly significant, because of the large volumes of air moved (hip roll-prone pressure, range 1,083 to 1,283 cc.; Nielsen, range 1,007 to 1,397 cc.), it is of interest that the most experienced operator (A. S. G.) obtained the best results, with the other four following in the order of their experience with these manipulations. This, logically, emphasizes the value of adequate indoctrination and experience. We must stress, too, the need for proper performance of the hip roll technic. The knee, fist or hand of the operator must always be placed under the hip close to him. Then, when the distant hip is lifted, it is in effect, "rolled" onto the knee, fist or hand. This elevates most or all of the abdominal surface from the horizontal. Without this, inadequate ventilation will most surely result.

The general observation was made that the ease of manipulation was much greater in the apneic subjects in this work, and the corpses in the previous work, than in the conscious passive volunteers. This consideration is of importance in the evaluation of fatigue resulting from the methods, since under practical conditions the subject will more closely resemble one of the former flaccid types. The hip lift-prone pressure method is most fatiguing. However, it can be executed at least during the crucial first few minutes of resuscitation, and when the operator becomes tired he is in the position to continue with the easier hip roll-prone pressure. If prolonged resuscitation is necessary by a single operator, he can still continue to use the Schafer prone pressure alone during short rest periods.

The subjects were asked to evaluate the efficacy of the various methods subjectively during the passive suspension of respiration. The arm lift-scapular pressure and the hip lift-prone pressure were considered to create the subjective impression of the most pulmonary ventilation. Several persons volunteered the information that the arm lift-scapular pressure method caused moderate distress in their shoulders. One subject noted slight pain in his back with the hip lift and the hip roll. Further questioning revealed a previous back injury. The Silvester method was commented on favorably by some, but it must be remembered that these were conscious subjects, and the possibility of oropharyngeal occlusion of the airway by the tongue in the supine position was not present here.

For the sake of completeness, both the eponymic and functional names of the various methods have been included in this discussion. However, it is strongly recommended that those methods lending themselves easily to functional names be referred to by such names rather than by the name of the originator or proponents. Almost a century of use has thoroughly entrenched the name of Silvester as applied to his method. However, all the other methods discussed herein have more appropriate designations: prone pressure (Schafer), hip lift (Emerson), hip roll (Emerson), rocking (Eve), arm lift-scapular pressure (Nielsen), arm lift-prone pressure (Drinker modification of Nielsen), hip lift-prone pressure (Schafer-Emerson-Ivy) and hip roll-prone pressure (Schafer-Emerson-Ivy).

Numerous mechanical devices are now available for the accomplishment of pulmonary ventilation, and most of these are superior to manual methods in situations requiring prolonged or special administration. But the first few minutes are crucial in resuscitation, and reliance on any such devices, which are not usually immediately available, can only lead to failures in attempts to restore respiration. A manual method, or mouth-to-mouth breathing, must always be used until an approved mechanical method is available.

---

[11] Artificial Respiration: Manual and Mechanical Methods, Royal Naval Physiological Laboratory, London, His Majesty's Stationery Office, 1950.

SUMMARY AND CONCLUSIONS

1. Eight methods of manual artificial respiration and the Eve rocking method have been evaluated with respect to the amount of pulmonary ventilation obtained on a series of 11 totally apneic normal adults. The results are compared with those obtained in the same group during passive suspension of respiration and also to those obtained in a previous study by the same operators on nonrigid warm corpses.

2. Results reveal that relative values of the various methods are completely corroboratory, except that the ventilation accomplished on the totally apneic subjects was approximately two times that on the warm corpses, whereas in the subjects with passive suspension of respiration the values were approximately three times those of the corpses. All methods utilizing a "push and pull," thereby causing active inspiration and active expiration, were approximately two times as effective as the "push" or "pull" methods alone, which result in only one half of each cycle being active.

3. It is noted that certain methods are better in specific body types. But, in the final analysis, the hip lift-prone pressure method is generally most efficacious. However, the hip roll-prone pressure method is much easier for sustained operation. The Nielsen (arm lift-scapular pressure) method produces comparable amounts of ventilation but may predispose to injury of the shoulders (although this has not been previously reported).

4. Any and all mechanical devices must always be considered as adjuncts to, and not substitutes for, manual methods, since the first few minutes are crucial for resuscitation and such devices are not usually immediately available

---

Radioactive Isotope Technics.—The nature of the radioactive isotope is such that it differs from its sister only in that it emits radiation and has a different atomic weight. Chemically it is no different But it immediately becomes possible to determine the rate of absorption of various elements, such as iron, sodium, copper and iodine, in extremely small quantities or tracer doses, and to differentiate in the tissue by extremely sensitive means, the element that had been administered to the animal during previous hours, from the amount of that element which was already present. Soon several technics for their use in such studies were developed. There is the so-called in vivo technic, in which a labeled or radioactive material or compound is located and measured in the living animal by means of counters placed over various parts of the body; second, sections of tissues are placed on sensitive x-ray films, and autoradiographs obtained of the site of deposition of the element in that tissue; third, the sample of tissue, urine or blood from a subject or animal is measured in the test tube or crucible under the counter at various intervals after the administration of the radioactive material. It was thus possible to get a dynamic picture of metabolism. In addition to the stable isotopic tracer technic, which was limited in its application to a few elements such as hydrogen, carbon, oxygen or nitrogen, the tracer technic was now extended to all the elements in the periodic table and the sensitivity of the method was much greater than the sensitivity of the methods using heavy or stable isotopes —John Hundale Lawrence, Clinical Use of Radioactive Isotopes, *Bulletin of the New York Academy of Medicine*, October 1950.

Clinical Notes, Suggestions and New Instruments

EPIDEMIC PAROTITIS COMPLICATED BY ACUTE SUPPURATIVE APPENDICITIS

Report of a Case

FRANCES ELIZABETH SCHAAR, M D.
Minneapolis

A few cases of acute appendicitis following the onset of epidemic parotitis have been reported.[1] The majority appear to be well established cases of mumps in which acute appendicitis developed five to seven days after the onset of the initial disease. They are to be differentiated from the cases with postoperative parotitis.[2] The question is periodically raised whether acute appendicitis developing in cases of epidemic parotitis has more than a coincidental relationship.

Reports [1] of five cases of mumps complicated by acute appendicitis have been encountered. In the more recent reports reference to four similar cases,[3] the first of which is reputed to have been described by Simonin in 1903,[3a] has been made. Various writers have reviewed their cases of appendicitis following infectious disease [4]

This case is presented to emphasize a possible, if only a coincidental, complication of mumps. Today a patient with mumps is considered by some to have a systemic disease,[5] and it is possible that the abdominal pain could initially be considered as a probable involvement of the pancreas.

This presentation is made, not to plead a causal relationship between mumps and acute appendicitis, but rather to stress the possible coincidence of the two conditions and to urge early diagnosis of the appendicitis.

REPORT OF CASE

C. S T., a man aged 21, noted swelling of the right parotid gland on March 24, 1948. He was hospitalized on March 26 It was then noted that both parotid glands were tender and swollen. The history and physical examination were otherwise essentially noncontributory. On admission, his temperature was 101.2 F. at 1:45 a. m., but it returned to normal by 7:00 a. m and remained normal for 48 hours. The admission laboratory tests showed a leukocyte count of 4,200, with 57 per cent neutrophils, 37 per cent lymphocytes, 2 per cent eosinophils and 4 per cent monocytes. He had a temperature of 102 F. and a headache on the evening of March 28. The next day he

complained of poor appetite and some abdominal discomfort. His temperature rose to 103 F. at 7:00 p. m. The parotid swelling had subsided; the abdomen was soft, and there were no positive findings. The leukocyte count was 6,000, with 49 per cent neutrophils, 42 per cent lymphocytes and 9 per cent monocytes.

His temperature was 100.4 F. at 3:00 a. m. on March 30 and was normal the rest of the day. He had a normal bowel movement. At 4:30 p. m. the abdominal pain returned. Examination revealed right lower quadrant tenderness, especially marked at McBurney's point, and tenderness on the right side by rectal examination. The leukocyte count was 16,700. A diagnosis of acute appendicitis was made, and an appendectomy was performed.

The operative report stated that there was a small amount of slightly cloudy fluid in the vicinity of the appendix, which was pointing down toward the pelvis. The appendix was described as being edematous, swollen and covered with fibrinopurulent exudate. There appeared to be an obstruction in the proximal third, and the base of the appendix was not inflamed.

The pathologist reported that the gross specimen consisted of an appendix 8.5 cm. in length and somewhat distended at the tip, with the distal third of the appendix measuring 1 cm. in diameter while the proximal half measured 0.5 cm. in diameter. The portions of appendix sectioned were the tip, middle and base.

Microscopic study of sections showed the presence of pus in the lumen with ulceration of the mucous membrane in many areas. There was a diffuse infiltration of all coats of the appendical wall by large numbers of neutrophils. There was marked edema of the submucosa, muscularis and serosal coat. The pathologist concluded that the patient had acute diffuse suppurative appendicitis.

The patient's subsequent hospital course was uneventful, and he was discharged April 3.

SUMMARY

A case of acute appendicitis developing on the sixth day following the onset of epidemic parotitis is presented. Reference is made to nine similar cases previously reported.

PERIARTERITIS OCCURRING DURING PROPYLTHIOURACIL THERAPY

ROBERT V. McCORMICK, M.D.[*]
New York

Reactions to propylthiouracil are uncommon but still occur, as evidenced by the reports of several authors, including Bartels.[1] Although periarteritis nodosa due to thiourea has been reported,[2] the following case is the first to show that propylthiouracil may cause fatal generalized periarteritis.

REPORT OF CASE

The patient, M. W., was first seen in the Roosevelt Hospital outpatient clinic in 1940, at which time she weighed 114 pounds (51.7 Kg.), had a blood pressure of 160/90 and a pulse rate of 100 with a regular sinus rhythm. When she was next seen, in March 1948, the blood pressure was 210/100, pulse rate 100, weight 106 pounds (48.1 Kg.), and an enlarged heart with a blowing systolic murmur at the apex was noted. Four months before entry the patient became hypersensitive and irritable after emotional trauma. One month before her entry to the Roosevelt Hospital it was noted in the clinic that her thyroid gland was palpable, and the basal metabolism rate was + 53 per cent. The patient was given 50 mg. of propylthiouracil four times daily; her pulse rate was 110 and her weight was 104 pounds (47.2 Kg.). The patient continued this medication for 10 days and then reduced the dose herself to one-half the recommended amount, because of gastric irritation. After an additional five days she stopped taking the drug altogether.

On the patient's return visit to the clinic fibrillation at a rate of 180 was noted. Immediate admission to the hospital was advised, and soon after the patient had been placed in the ward she was found to have a blood pressure of 130/60; the pulse was grossly irregular and the rate 136. She was an emaciated, elderly woman who appeared chronically ill, and had a coarse tremor of the hands. The eyes appeared to protrude, but this had been characteristic of the patient for 20 years prior to examination. The thyroid gland was barely palpable. The patient had a few rales of congestive failure at both lung bases. Examination of the heart revealed moderate enlargement, a blowing systolic murmur and auricular fibrillation. The patient had no evidence of peripheral edema, and reflexes were normal; there were no Babinski reflexes. The laboratory data revealed the patient had 12 Gm. of hemoglobin and 4,400 white blood cells, with 76 per cent polymorphonuclear neutrophils and 22 per cent lymphocytes. The blood cholesterol was 172 mg. The serologic reactions of the blood to the Kline exclusion test and Mazzini test were negative.

Bed rest was prescribed, and the patient was given digitalis and sedatives for the first few days in the hospital in an attempt at evaluation of the true degree of hyperthyroidism and cardiac failure. On the third hospital day the basal metabolic rate was + 25 per cent. Because of this pronounced drop in the basal metabolic rate (three basal metabolic rates in the clinic at the time of onset of therapy were + 53, + 59 and + 55 per cent) and because the history and signs and symptoms were not altogether typical of classic hyperthyroidism, no specific therapy was employed. Nine days later the basal metabolic rate was + 12 per cent. This did not persist, and further basal metabolic tests revealed a level of + 31 per cent. It was felt that the patient's age and condition made her a poor operative risk, so that continued medical therapy was indicated; she was again given propylthiouracil. The temperature of the patient was normal before the administration of propylthiouracil (50 mg. four times daily) but within the following 24 hours rose to 103.4 F. Diarrhea also developed, but no other abnormal signs were present. Approximately 36 hours after the administration of the drug the patient became incontinent and unable to care for herself. She had difficulty forming words, became irrational, showed a left facial paresis with weakness and had a Babinski reflex on the left side. As it was felt at this time that the patient was suffering from a cerebral vascular accident, a spinal tap was done, which revealed normal pressure, crystal clear fluid, no white cells, a protein level of 16 mg. per 100 cc., a colloidal gold reaction of 1111100000 and a negative Wassermann reaction. At that time the patient had a white blood cell count of 7,150, with 90 per cent polymorphonuclear neutrophils, 9 per cent lymphocytes and 1 per cent monocytes. On the fifth day of this episode it was noted that all the symptoms of fever, diarrhea and left hemiparesis had become apparent within 24 hours after the administration of the propylthiouracil; therefore treatment with this drug was stopped. Within 24 hours the patient's temperature was normal, the diarrhea had stopped, the Babinski reflex had disappeared, and she appeared greatly improved and became rational.

It was felt that the patient was sensitive to this drug; she was therefore allowed to recuperate for one week, during which time she had no symptoms and had a normal temperature. A test dose of 50 mg. of the drug was then given. Within 12 hours her temperature rose to 101.2 F., diarrhea developed and she had pronounced weakness and mental confusion. These symptoms disappeared after 24 hours had elapsed, and the patient continued asymptomatic until the time of discharge. Medication prescribed at this time consisted of sedatives and digitalis. Because she was a poor operative risk, her hyperthyroidism was not severe enough to warrant operation, and because her severe reaction to propylthiouracil had contraindicated that drug, it was hoped the patient's condition could be controlled with iodine on an outpatient basis.

The patient was followed in the clinic for two months, during which time she was asymptomatic. She was then inadvertently again given propylthiouracil, 50 mg. four times daily, six days before the second admission to the hospital. She had taken a total of 1,150 mg. of the drug before she was brought to the hospital in an unconscious condition, which had its onset two hours before admission. At this time the patient had a blood pressure of 165/82 with a pulse rate of 128, with regular sinus rhythm. The patient had evidence of a left cerebral vascular accident, left facial weakness and a left Babinski reflex, but a spinal tap revealed no abnormalities. Supportive therapy was given, but the patient remained in this condition without appreciable change and died six days after admission without having gained consciousness.

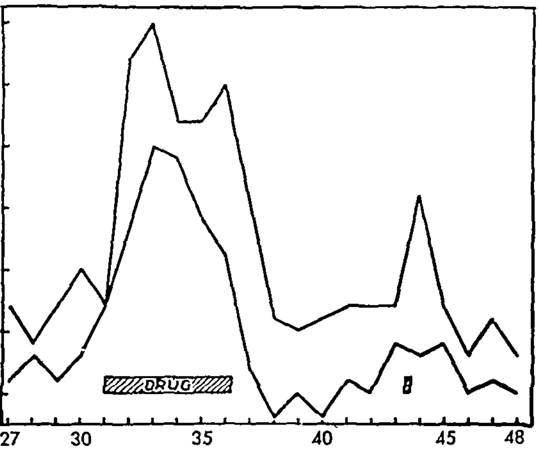

Fig. 1.—*Minimum and maximum temperatures during the administration* of propylthiouracil. The therapeutic dose was 200 mg. every 24 hours. The test dose was 50 mg. The ordinate represents rectal temperature (Fahrenheit) and the abscissa indicates day of hospitalization.

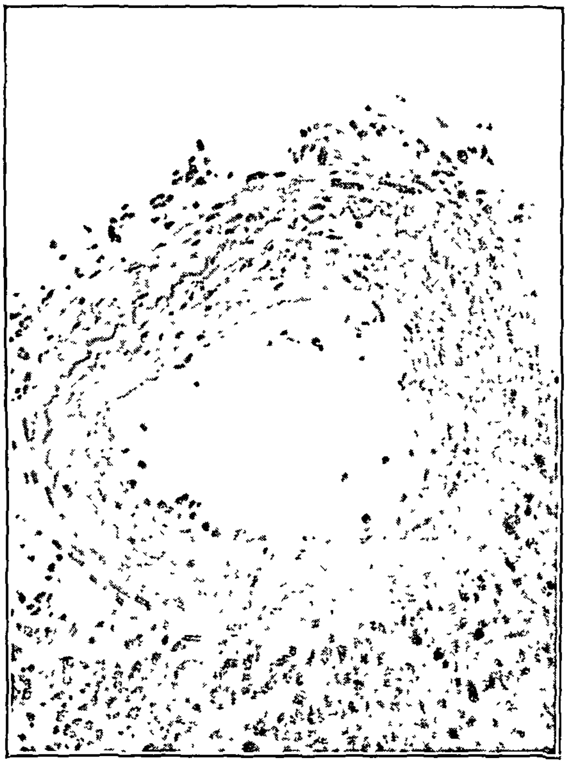

Fig. 2.—Section of the liver (× 500) showing the wall of a small artery with cellular infiltration, hyalin necrosis and edema.

Postmortem examination revealed that the brain weighed 1,220 Gm. A recent thrombus occluded the lumen of the right middle cerebral artery. The thrombus was about 3 cm. in length. Further gross examination of the brain revealed no abnormality. The heart weighed 285 Gm., and the mitral valve measured 8 cm. in circumference; several of the chorda tendineae were thick and retracted. The free edge of the anterior leaflet was greatly thickened and calcified, and bone formation in one area was noted. Multiple sections of the myocardium revealed no area of infarction. The thyroid gland weighed 20 Gm. and was formed of small nodules, which revealed cystic degeneration on sections.

Dr. W. W. Brandes, pathologist of the Roosevelt Hospital, reported that microscopic examination of the organs revealed diffuse periarteritis. In the liver there was pronounced arteriolosclerosis, and the walls of the arterioles were swollen and edematous, with areas which were broken and granular in appearance. Hyalin necrosis of both arterioles and small capillaries, infiltration with lymphocytes, neutrophils and a few eosinophils, terminal passive hyperemia and fatty metamorphosis with areas of vacuolization of the liver cells were observed. There was pronounced nephrosclerosis, with changes similar to those noted in the arterioles of the liver, in the slides of the kidney. The thyroid sections revealed fetal adenomas with colloid involution and many areas of hyperplasia and involution. Sections of the brain revealed edema and pericapillary hemorrhages; a few of the capillaries were distended with leukocytes. Similar vascular changes were noted in the pancreas. The heart showed a mild accumulation of lymphocytes, an occasional neutrophil and some eosinophils around some of the smaller vessels. The walls of some of these vessels were thickened, and the substance was granular, obliterating to some extent the normal architecture. There were no typical lesions of rheumatic involvement.

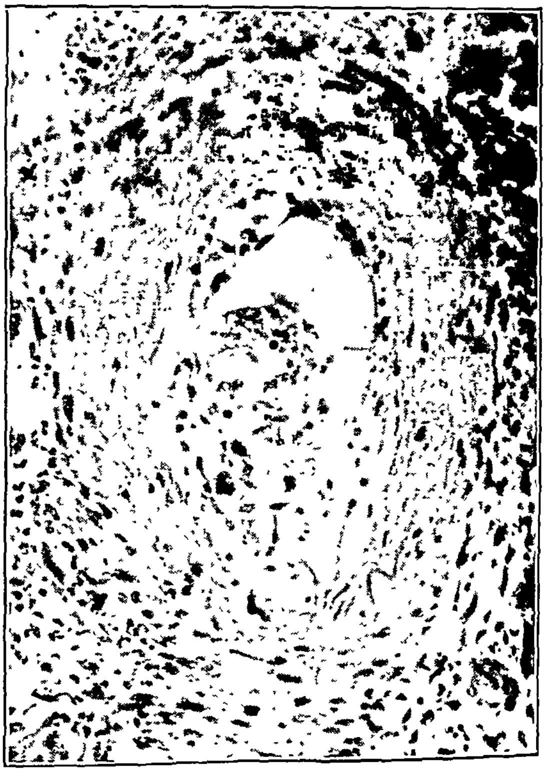

Fig. 3.—Section of a small artery of the kidney (× 500) showing pronounced edema, necrosis and cellular infiltration.

SUMMARY

A fatal case of a diffuse periarteritis due to propylthiouracil reaction, manifested by signs of a left hemiplegia, nausea, vomiting, fever, mental confusion and a normal white blood cell count, is reported.

428 West Fifty-Ninth Street.

REPORT OF THE COUNCIL

The Council on Physical Medicine and Rehabilitation has authorized publication of the following report.

HOWARD A. CARTER, *Secretary.*

ARTIFICIAL RESPIRATION

A New Method and a Comparative Study of Different Methods in Adults

ARCHER S. GORDON, M.D.
DAVID C. FAINER, M.D.
and
A. C. IVY, M.D.
Chicago

Studies on the efficacy of the various methods of artificial respiration abound in the literature. However, a comparative study of a number of current methods by the same group of observers, using a significant number of nonrigid human corpses, is not available.

CHOICE OF SUBJECTS

Four types of subjects have been used for the study of the efficiency of various methods of artificial respiration: (*a*) human corpses prior to the occurrence of rigor mortis, (*b*) normal passive human subjects with "voluntarily suspended respirations," (*c*) deeply anesthetized and/or curarized animals, (*d*) human subjects deeply anesthetized or curarized, or apneic for some other reason. There have been investigations in which one or more of these methods have been used.[1] However, the results of different investigators and methods vary widely; the authors fail to consider all currently advocated manual and mechanical methods and usually report only a few cases.

Laboratory animals were not used by us for this study because the anatomy of a dog or that of a monkey renders results obtained equivocal. Since we desired to perform relatively many tests, the risks, though remote, associated with the deep anesthetization and/or curarization of otherwise normal human volunteers deterred us from using this type of subject. We decided to use subjects who were instructed to "voluntarily suspend their respiration" in some tests but not in many, because, as is realized by many investigators in this field, the results so obtained are equivocal in that such a subject is not comparable to a person requiring artificial respiration.[2] Therefore, for most of our tests we used recently deceased, warm corpses, prior to the onset of rigor mortis. We believe, as suggested by Eve,[3] that such a subject is most comparable to a person requiring artificial respiration, except perhaps the deeply anesthetized apneic person.

METHODS OF ARTIFICIAL RESPIRATION STUDIED

Readers interested in the history of the development of artificial respiration from early ages to the present day can find many excellent references[4] (fig. 1). The methods are usually classified as manual or mechanical. The term mechanical indicates that some sort of apparatus or device, even though only a board or stretcher, is used. Of the many manual methods proposed, only those in use today or believed to be efficacious were considered in this survey.

Manual Methods.—Silvester Method[5] (1858): The patient is placed in the supine position with the arms at the sides and forearms and hands on the lower part of the thorax. The arms are raised and straightened and extended over the subject's head to effect active inspiration and then returned to their original position, making pressure on the thorax to produce active expiration. The method has the disadvantage of frequent occlusion of the airway by the tongue's falling backward into the pharynx. Ribs have been fractured by the exertion of too much pressure[6]

Schafer (Prone Pressure) Method[7] (1903): The patient is placed in the prone position with arms extended and face to one side. Pressure is exerted with the hands close together on the lower portion of the thorax. The pressure on the thorax causes active expiration, and inspiration occurs passively as the result of elastic recoil. The maneuver requires little muscular exertion by the operator. This is the most widely used method because of its simplicity.

Nielsen Method[8] (1932): The patient is placed in the prone position with his hands under his forehead. Several slaps are administered between the shoulder blades to force the tongue out of the pharynx. The elbows are grasped and raised to cause active inspiration; they are then released, and pressure is exerted over both scapulas to produce active expiration. Undue pressure may fracture the ribs.[9]

Schafer-Nielsen-Drinker (Modification of Nielsen) Method[10] (1935): The patient is placed in the Nielsen position. One operator performs the prone pressure procedure of the Schafer method while another operator alternately raises the elbows or arms. Drinker thus eliminates the pressure exerted over the scapular area in the Nielsen method, which he believes may cause fractures of the ribs. At the same time it retains the well

known features of the Schafer method. Drinker was the first in this country to suggest this modification, although he was preceded a few months by Héderer in France.[11]

Emerson Method[12] (1948): Mr. John H. Emerson has proposed that the hips be lifted and lowered with the patient in the position of the prone pressure method. Raising the hips several inches causes active inspiration because of descent of the inert diaphragm and hyperextension of the spine (as verified by us fluoroscopically and radiographically). Lowering of the hips results in passive expiration. Mechanical devices are also available for executing this method.[13]

Schafer-Emerson-Ivy (Hip Lift-Prone Pressure) Method: With the patient prone, this method alternates the lifting and lowering of the hips (as in the Emerson method) with pressure exerted on the lower part of the thorax (as in the Schafer method). Early muscular exhaustion may be avoided by the use of a piece of cloth, a shirt or a belt, passed beneath the hips, so that the lifting may be conducted by one or two persons while another carries on the prone pressure maneuver. Thompson[14] in 1935 reported the use of this hip lift-prone pressure method in an 18 year old victim of acute paralytic poliomyelitis. The victim was gasping, cyanotic and unconscious when artificial respiration was begun. The Schafer method failed to produce adequate ventilation, and the paralysis reduced elastic recoil of the chest so that it remained in relative expiration. Hip Life-Prone Pressure resuscitation was used for eight hours and kept the patient semiconscious and ventilated until a respirator was secured. The victim recovered.

Hip Roll-Prone Pressure Method: Subsequent to the completion of the major portion of this study, a modification of the hip-lifting technic was suggested. In order to reduce the fatigue incident to lifting the hips, it appeared that elevation of only one hip would produce active inspiration with less effort. In effect the victim is grasped at the distant hip and "rolled" onto the rescuer's knee. This can be accomplished alone or in conjunction with Schafer prone pressure.

Mechanical Methods.—Eve (Rocking) Method[15] (1932): The patient is placed in the prone position and is rocked in a head-down and then feet-down position. Unlike the manual methods, the rocking method depends solely on the up and down motion of the diaphragm produced by the movements of the abdominal viscera during rocking.

Automatic Intermittent Positive Pressure: This method expands the chest by intermittently introducing air or a gas mixture under pressure (up to 20 cm. of water or 14.7 mm. of mercury in this work) into the upper respiratory passage via a face mask. A Burns valve[16] was used for this purpose by us, though there are other good positive pressure devices.

Alternating Negative and Positive Pressure (Suck and Blow): We used several devices that provided a positive pressure of + 14 mm. of mercury and a negative pressure of approximately − 9 mm. of mercury via a face mask.

METHODS FOR RECORDING VOLUME OF PULMONARY VENTILATION

The efficacy of an acceptable method for artificial respiration depends first and foremost on the speed with which it may be applied to the patient after he is found; second, on the relative adequacy of the volume of pulmonary ventilation it produces; third, on whether it has a beneficial, indifferent or harmful effect on cardiac output and cerebral blood flow; fourth, whether it tends to open or close the airways; fifth, on its ease of application; sixth, whether it predisposes to regurgitation and aspiration of stomach contents, and seventh, on whether it is harmful to the lungs or exposes to dislocation of the shoulder or fracture of the ribs. In the major portion of this study, we were interested in the second factor, namely, the amount of pulmonary ventilation really obtained by the various methods.

With the manual methods and the rocking method of Eve, the minute volume of air exchange was measured by having the corpse inspire and expire into a carefully balanced graphically recording calibrated spirometer. With the mechanical methods, a very sensitive and accurate flow meter was used to record the volume of air exchange. The volume recorded by the spirometer was cross checked through the flow meter. However, the small inertia factor in the latter may have resulted in slight reduction of the mechanical values obtained. The dial of the flow meter was modified so that a kymographic record could be made of the amount of air exchanged with each respiratory movement.

For the unequivocal comparison of the amount of pulmonary ventilation produced by the different methods, we kept the airway open by introducing and using a McGill endotracheal tube with an inflatable cuff. This yielded an air-tight fit, reliable results and an ideal airway.

We also used during this study an ordinary anesthesia mask, which was attached to the recording devices. In some cases leakage occurred around the mask, and it was not easy to keep the chin in the mask during the various maneuvers; the results on the volume of respiration were therefore inaccurate. Subsequently, we used a full face gas mask with an inner rubber flap to insure against leakage with positive pressure. This mask supported the chin, kept the mandible elevated and prevented the tongue from falling into the oropharynx. Under the practical conditions of resuscitation one is not concerned with a small amount of leakage, but we were anxious to prevent leakage because we were measuring the minute volume of pulmonary ventilation.

To simulate natural, practical conditions as closely as possible and to allow the mandible free movement, an additional method was used in which the nostrils were closed with a clip and the lips with a mouth piece. The mouth piece was devised with a central opening 1 inch (2.5 cm.) in diameter surrounded by a gingival and external flange which could be tightened on the lips, yiending an air-tight system when the central opening was attached to the spirometer or flow meter.

GENERAL PROCEDURE

A day and night call system was arranged with the hospital to provide prompt notice of a preterminal patient. All cases of known preterminal pulmonary pathology were excluded. Otherwise the warm corpses represented a random sampling of the adult male and female deaths at the hospital.

We decided to make all tests within one hour after cessation of the heart beat. However, it was found that in certain corpses rigor mortis started to develop within an hour; the data on these cases were excluded. It was also found that in some corpses rigor mortis did not develop for much longer than an hour and hence could be used for study for a longer period. However, the data we report for comparison includes only data that were obtained within 90 minutes, mostly within 60 minutes, after death, and considerably before the onset of rigor mortis. Calls were answered for over 200 cases, but the data for only 109 are submitted in this report. The others were eliminated for various reasons, such as too rapid onset of rigor mortis, tuberculosis, arthritis, deformities and occlusion of the tracheobroncheal tree by dense mucus, detritus or tumors.

It was not possible, of course, to rule out corpses with some pulmonary edema, passive congestion, bronchopneumonia and collections of mucous secretion. Such conditions in a corpse probably decreased the volume of pulmonary ventilation as compared with a corpse with completely clear lungs, but each corpse was exposed to an entire group of manual or mechanical methods in a regular order and under the same conditions; hence the comparative values are unequivocal. (Indeed, the results obtained on corpses with mild degrees of lung pathology might be more applicable to drowned persons). Within a given series each manual or mechanical method of artificial respiration was used on each corpse. The various methods were kept in a definite sequence and rotated according to a fixed schedule, so that each method was applied in turn after death an equal number of times.

RESULTS

Comparison of Manual Methods and the Rocking Method.—Airway with Endotracheal Intubation: Table 1 shows that the various manual methods and the rocking method of Eve may be divided into two groups. One group yields approximately twice as much ventilation as the other.

The manual methods which are designed to assist actively both inspiration and expiration produce twice as much ventilation as those that do not. In other words, it is not enough to compress actively the chest to get air out; it is also necessary to expand actively the chest to get air in. The double activity may be referred to as "push and pull." This point is shown clearly in the pneumograms (fig. 1) made of the respiratory cycle from the spirometer records. Lifting the hips, as in the Emerson method, causes an active inspiration and a passive expiration of approximately the same amount. In the Schafer prone pressure method the converse is true, since the active expiration is followed by a passive inspiration of approximately the same volume. The "push and pull" methods, such as the hip lift-prone pressure method of Schafer, Emerson and Ivy, consist of the cyclic sequence of (*a*) active inspiration, (*b*) passive expiration, (*c*) active expiration and (*d*) passive inspiration, and approximately twice as much ventilation occurs as with a maneuver which includes only half of the sequence.

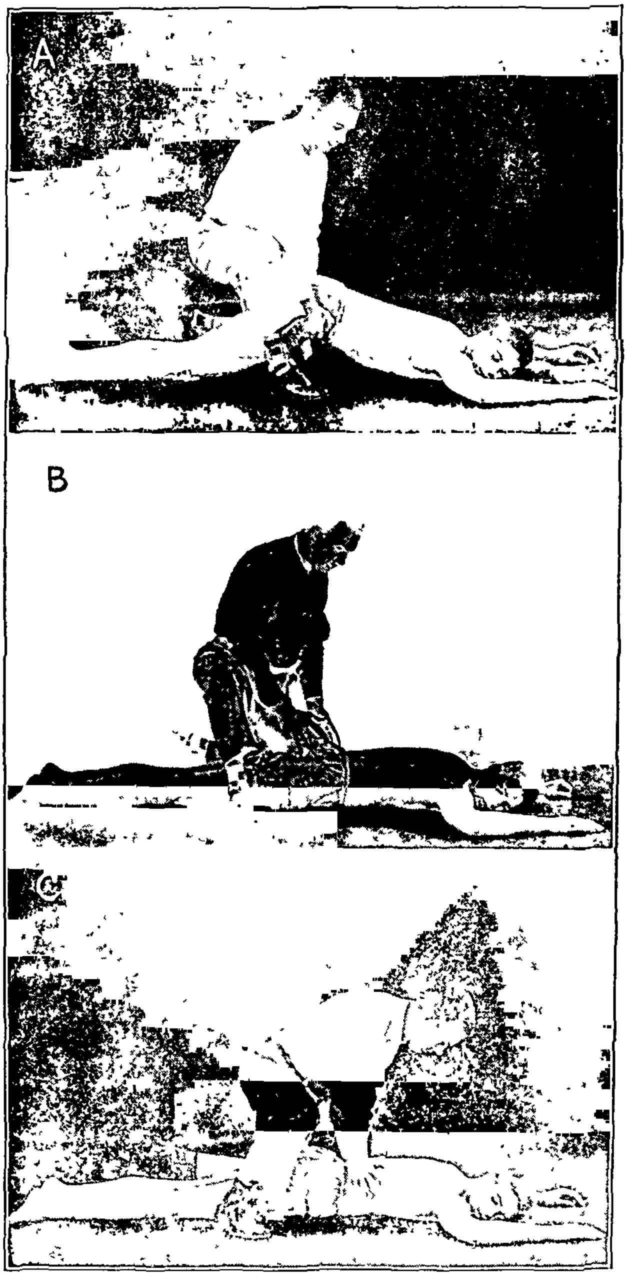

Fig. 2.—Schafer Emerson-Ivy hip lift-prone pressure method from optimum Schafer position. *A*, elevation of hips to cause active inspiration. *B*, replacing hips after active inspiration and preparing to execute prone pressure. *C*, prone pressure over floating ribs to cause active expiration.

The values in table 1 may be compared with the values for tidal air and minute volume for the average, healthy, normal, living adult subject, which are 500 cc. and 6,000 cc. per minute at rest,[17] respectively. The air exchange of 185 cc. obtained by the Schafer method is adequate for the minimal tidal air for resuscitation proposed by Swann,[18] namely, 2.5 cc. per kilogram of body weight, or 175 cc. for a person weighing 70 Kg., but a much larger tidal air is preferable.

Since the air exchange obtained with the Eve method depends on the excursion of the diaphragm which is dependent on the range of movement of the viscera produced by gravity, the air exchange during one respiratory cycle will depend on the arc through which the patient is rocked.[19] Five warm corpses were used to check this supposition, since it has been proposed by some that rocking should be first through an arc of 50 degrees, then 40 degrees and, finally, maintained at an arc of 30 degrees. Rocking at a rate of 12 times per minute, we obtained the following minute volumes of air exchange: at an arc of 30 degrees, 115 cc., or a minute volume of 1,380 cc.; at 40 degrees, 210 cc., or a minute volume of 2,520 cc., and at 50 degrees, 300 cc, or a minute volume of 3,600 cc. We confirmed the observations of Pask[2b] and Gibbens[11] also, in that we found that the "jerk," instead of a smooth change, at the end of each "swing" increased the ventilation slightly as might be expected.

TABLE 1.—*Results Obtained with Manual Methods and the Rocking Method in Twenty-Six Warm Human Corpses (Endotracheal Airway)*

	Single Respiratory Cycle			
Procedure	Average, Cc.	Range, Cc.	Methods Compared, % *	Minute Volume, Cc., Rate 12/Min
Prone rocking (Eve) †	225	50-572	42	2,700

19. Cowan, S. L.: Artificial Respiration with Special Reference to the Rocking Stretcher Method, and Trials with a "Riley Rocking Stretcher," Medical Research Council, Royal Naval Personnel Research Committee, London, His Majesty's Stationery Office, 1949.

In studying the Eve method with respect to the rate of rocking on the volume of each cycle and on the minute volume of air exchange, we found that rocking at a rate of eight times per minute increased the volume of each cycle but not the minute volume as compared with 12 times per minute. When the rate was increased to 18 times per minute, the volume of each cycle was decreased so that the minute volume remained the same or was only slightly increased. At 30 times per minute the volume of each cycle was decidedly reduced and the diaphragm tended to remain in a state of sustained inspiration. However, to graph or mathematically express the relation between the rate of rocking plus the size of the arc on the volume of air exchange per cycle and per minute would require more study than we thought the problem warranted. The optimum is approximately 12 to 15 per minute through an arc of 50 degrees.

The rocking method of Eve was also studied with the same warm corpse in both the prone and supine positions.[19] Nine cases were used, and the exchange in the prone averaged 225 cc. and in the supine 200 cc. This was done, of course, with the endotracheal airway and would not hold for the supine position if another airway were used, because of occlusion with the tongue or secretions.

§ Hips elevated 3 to 4 inches 12 times per minute

With the Emerson method, the effect of raising the hips to varying degrees was studied. It was thought that a small elevation might cause only a negligible inspiration, whereas excessive elevation, aside from being exhausting, might cause the abdominal viscera to slide cephalad and cause active expiration by pressure on the diaphragm as in the rocking method. Neither of these suppositions was verified by the results.

In eight corpses it was found that elevation of the hips of 2 inches (5 cm.) yielded an average inspiration of 217 cc., and of 6 inches (15 cm.), 320 cc.; when the hips were raised to make a 45 degree angle between the body and the horizontal, the inspiration amounted to 400 cc.; at 80 degrees the figure was 470 cc.

In a subsequent series on eight warm corpses in which the Emerson hip lift was compared with the hip roll method, the former produced twice as great a tidal volume as the latter (table 2). However, combination of the roll with the Schafer prone pressure method yielded 76 per cent of the ventilation accomplished by the hip lift combined with the Schafer and almost twice as much as the Schafer method alone.

Natural Airway with Full Face Mask: The full face mask was used on eight corpses, with results shown in table 3. The results closely conform to those obtained with an endotracheal airway (see table 1). In one of the eight corpses, only three of the six methods tried produced any air exchange, namely, the hip lift, the hip lift-prone pressure and the rocking methods. No explanation could be found for the failure of the other methods in this case.

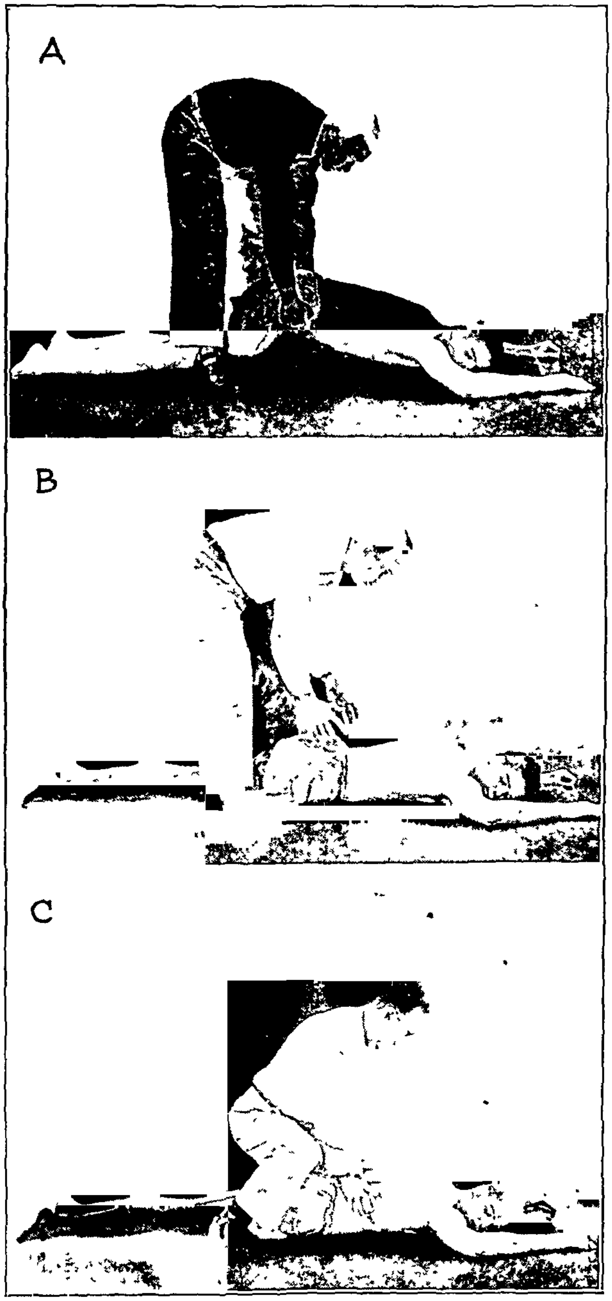

Fig. 3.—The Schafer-Emerson-Ivy method, "push and pull," from the standing position. *A*, elevation of hips to cause active inspiration. *B*, replacing hips and preparing to execute prone pressure. *C*, pressure on floating ribs to cause active expiration.

Airway Made with a Mouth Piece: The mouth piece was used with the nostrils closed by a clip to provide an air-tight airway and at the same time to permit the tongue and mandible to remain free, in order that we might obtain some information regarding how frequently they would interfere with air exchange.

This was studied in eight corpses. Air exchange was obtained in only half the cases with the Silvester (supine) method but in three fourths of the cases with the hip lift and prone pressure methods. The hip lift-prone pressure method and the arm lift-prone pressure method obtained air exchange in every case The data on the air exchange in those cases in which it was obtained are shown in table 4. The superiority of the two prone "push and pull" methods is evident.

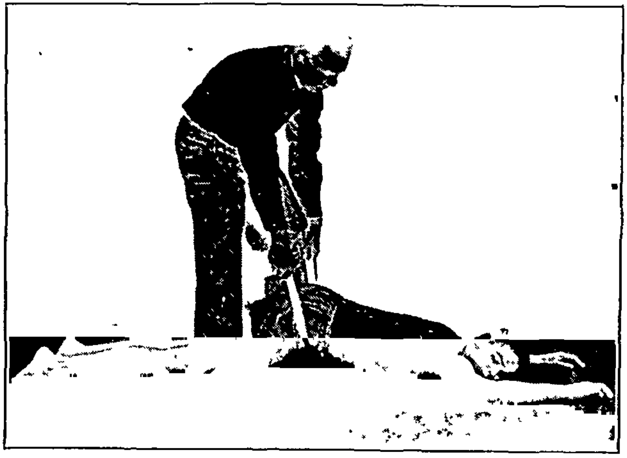

Fig 4.—Use of a belt to assist in the hip-lifting technic of Emerson.

The results of this phase of our work certainly emphasize the importance of the maintenance of an open airway. Even in our presumably skilled hands the prone pressure method failed to produce any measurable air exchange in one fourth of the cases, apparently because of a failure of adequate elastic recoil of the chest.

Natural Airway with an Anesthesia Mask: This is the type of mask that is generally used for giving artificial respiration by mechanical methods. The mask will leak unless held firmly on the face. The natural airway will become obstructed readily unless the mandible is held firmly forward and against the maxilla and the face to one side. Although it gives less accurate results, because of possible leakage of air, this method also proves the superiority of the hip lift-prone pressure method (table 5).

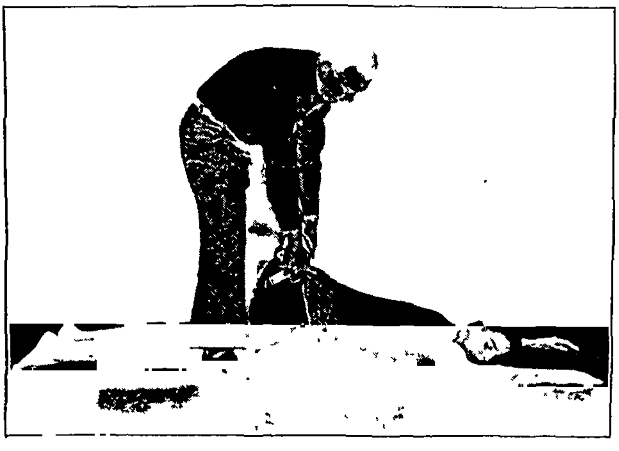

Fig. 5.—Use of victim's trousers to elevate hips as part of the Schafer Emerson-Ivy method of artificial respiration.

MECHANICAL METHODS

The use of the alternating negative and positive pressure ("suck and blow") and the automatic intermittent positive pressure resuscitators was rather simple. The mask was placed on the face with the mandible and face held in the appropriate position, and then the flows were recorded under various pressures (fig. 7).

The automatic intermittent positive pressure device (Burns' valve) was used on eight warm human corpses with the following averaged results: At pressures of 6, 9 and 12 mm. of mercury rates of 59, 37 and 30 cycles per minute, respectively, were obtained with an air exchange of 16, 51 and 107 cc., respectively, per cycle. When the Burns valve was operated at a pressure of 14.7 mm. of mercury, it performed at an average of 25 cycles per minute with an average air exchange of 185 cc. per cycle, the minute volume of ventilation being 4,625 cc.

Use of the alternating positive (+ 14 mm. of mercury) and negative (— 9 mm. of mercury) pressure resuscitator on these eight corpses resulted in an average rate of 21 cycles per minute with an average air exchange of 216 cc. per cycle, the minute volume of ventilation being 4,536 cc. Thus, operating at the same pressures, the two devices yielded approximately the same results.

* Millimeters of mercury measured at the apparatus.
† Normal average values equated at 100 per cent: tidal air = 500 cc.; minute volume = 6,000 cc.

Table 6 shows the average and ranges of the results. An inadeqate ventilation or obstructed airway was not observed with mechanical respiration in eight cases in this work or in 16 other cases studied several years ago by Schwerma and Ivy.[20]

Results on Subjects with Voluntary Suspended Respiration.—This method was employed because so many investigators have used it and we desired to compare the results we obtained in corpses with those we might obtain by this method. The nine volunteers for this phase of our study were medical or graduate students. They were given instruction in the performance of the various manual methods of artificial respiration and in suspending respiration after a short period of hyperventilation. Training is required to "learn not to breathe." [18] Each method was then performed on the volunteer until he showed a regular pattern in the pneumogram from the spirometer, a basal metabolism test mouth piece and nasal clip being used. The volunteers had no knowledge of the results we had obtained on corpses by the various methods. In fact, we ourselves had not summarized our results when the volunteers were studied.

The results are shown in table 7. Comparison of results shows that they are essentially in agreement, except that the volume of air exchange is four times greater in the volunteers than in warm corpses (table 1). The "push and pull" methods in these volunteers yielded about twice as much air exchange as either a "push" or "pull' method alone. In a similar survey on passive volunteers Thompson [11] obtained two to three times as much ventilation with the hip lift-prone pressure method as with the Schafer method.

---

[20] Unpublished data.

Either the volunteers unconsciously aided the artificial maneuvers or there is less resistance in the conscious person to respiratory exchange. Numerous invalidating criticisms may be raised against this sort of experiment. Even though the results agree in general with those on the warm corpses, we are inclined to place much more weight on the results from the corpses and to consider them applicable in resuscitation of near-dead asphytic subjects.

Silvester [5] and Burns [1a] successfully used warm corpses before the onset of rigor mortis, within two hours after death, but Schafer,[6] Bolton [21] and Drinker [22] were unsuccessful in their attempts. The lack of success is easily understood by us and will be experienced by others unless they have their apparatus set up in the hospital and stand by day and night for a call from the attending nurses

Table 7.—*Results on Nine Normal Subjects with Suspended Respiration After Hyperventilation by Various Manual Methods and the Rocking Method*

Pask [2b] reports a single case in which the intubated subject was anesthetized with thiopental sodium and ether and rendered apneic by forced ether inhalation. He found similar values for pulmonary ventilation (range 331 to 394 cc.) with the Schafer, Silvester and Eve methods when the subjects were rocked 30 degrees in each direction in the prone position or 45 degrees in the supine. When they were rocked 45 degrees in each direction in the prone position the values were higher (559 to 580 cc.). On a single anesthetized and curarized subject, Pask again found the Eve method superior and suggested that the rocking method may assist blood circulation (as inferred from oxygen consumption).

EASE OF PERFORMANCE OF MANUAL METHODS

The nine volunteers were asked, after they had received considerable instruction on the performance of the various methods, to assess the relative ease of performing them for a period of time that might be required in resuscitation. According to their assessment the methods fell into three groups.

Group 1 included those methods requiring little effort. The Schafer and Eve methods are in this group. Group 2 included the methods which are moderately exhausting but could be continued for a physiologically reasonable period by almost every operator under emergency conditions. The Silvester, the Schafer-Nielsen-Drinker and the Nielsen methods are in this group. Group 3 included the methods which are exhausting and could not be performed over a prolonged period, but could be prolonged over a physiologically reasonable period by almost every operator under emergency conditions. The Emerson and the Schafer-Emerson-Ivy methods belong here because the operator must lift the body at the hips. After indoctrination in performing the hip lift-prone pressure method from a kneeling position, the majority preferred this to the sole maneuver of lifting the hips. However, in the subsequent series, in which the hip roll-prone pressure method (fig. 6) was evaluated for efficacy of ventilation and ease of performance, it provided three-quarters the air exchange of the hip lift-prone pressure method and was notably easier of performance. It would readily be classified in upper group 2—almost in group 1

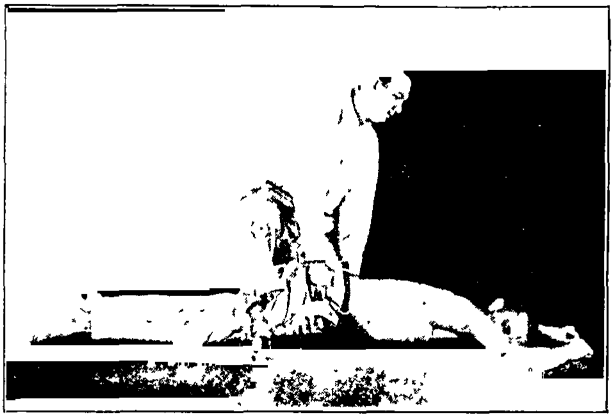

Fig. 6—The hip roll modification of the hip lift method

COMMENT

Our results reaffirm the fact that no one method of artificial respiration can be offered as completely satisfactory. We have therefore listed in table 8 the advantages and disadvantages of the rocking method of Eve and each of the manual methods included in our study. However, there can be no doubt regarding the observation that those manual methods which utilize both a "push and pull" maneuver are superior. As regards the amount of the air exchange obtained, there is not enough evidence available in our work or in the literature to warrant a conclusion that any one of the "push and pull" methods is superior to the other. It is noteworthy that each of the "push and pull" manual methods, as well as both mechanical methods used, produced a minute volume of 5,000 to 6,000 cc This is

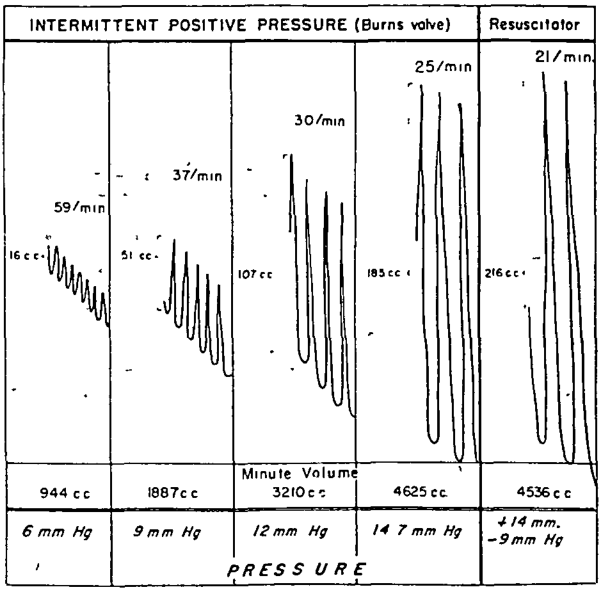

Fig. 7—Graphic representation of respiratory patterns obtained with various settings of intermittent positive pressure (Burns' valve) and "suck and blow" resuscitator devices

an optimum amount; more would result in the disadvantages of hyperventilation.

---

[21] Bolton in Schafer.[6]
[22] Drinker, C. K: Personal Communication to the authors.

Except for the armamentarium of the anesthetist and of the fire or police emergency crew, all mechanical devices must always be considered as adjuncts to and not substitutes for manual methods. This is especially true in view of the effectiveness of the "push and pull" manual methods; in other words, the mechanical resuscitators employed in this study (when operated at mask pressures of + 14 mm of mercury positive pressure and — 9 mm. of mercury negative pressure or at an intermittent positive pressure of + 14 mm. of mercury) are not more effective than a properly performed "push and pull" manual method. The properly employed mechanical resuscitator requires less skill than a properly performed "push and pull" manual method, is not fatiguing and can deliver pure oxygen; herein lie the most important advantages of a good mechanical resuscitator. There are other advantages, however[23] Since a resuscitator need be applied only to a patient's face, it can be employed where physical manipulation of the body is impossible or would be harmful, as during major surgical procedures, in accident cases with extensive burns, broken vertebrae, ribs and arms, for victims trapped under debris of excavations or overturned vehicles and during transportation to a hospital. The resuscitator further signals when the airway is obstructed and provides an aspirator.

TABLE 8—*Advantages and Disadvantages of Manual Methods and Eve (Rocking) Method*

Advantages	Disadvantages
SILVESTER	
1 Started immediately	1 Patient supine; airway can become obstructed
2 Requires only one rescuer	2 Fracture of ribs and rupture of the liver reported
3 Requires no apparatus.	3 Moderately exhausting
4 Provides good pulmonary exchange	4 Probably requires specially trained personnel
SCHAFER	
1 Almost universally known and taught	1 Tidal volume not large '
2 Simple to learn.	2 Fractures of ribs reported
3 Performed by anyone (including women and children)	3 Active expiration with only passive inspiration
4 Performed for indefinite periods of time	
5 Excellent results reported	
6 Requires no equipment	
7 Instituted immediately.	
8 Uses prone position.	
9 Requires but one rescuer.	
EVE	
1 Simple to learn	1 Requires proper apparatus
2 Performed by anyone	2 Time lost setting up apparatus if alone
3 Performed for indefinite time	3 Tidal volume not large
4 Accessory treatment can be carried on simultaneously	4 Stomach contents may be poured up into pharynx and subsequently aspirated
5 No fractures of bones, or ribs.	
6 Uses prone position	
7 Requires one rescuer to rock (but at least two to three to set up without neglecting patient)	
NIELSEN	
1 Requires one rescuer only.	1 Not well known
2 Started immediately	2 Moderately fatiguing
3 No appliances required.	3 May cause shoulder injuries or fracture of ribs
4 Prone position used	
5 Provides excellent exchange	
SCHAFER NIELSEN DRINKER	
1 Similar to established Schafer *method*	1 Requires two operators to complete *operation*
2 Can supplement Schafer method	2 May cause shoulder injuries
3 Uses prone position	3 Moderately fatiguing
4 Provides excellent exchange	
5 Performed immediately	
6 No apparatus required	
SCHAFER EMERSON IVY	
1 Easy to learn	1 Difficulty in lifting hips for long periods of time
2 Same position as Schafer	
3 Can be used to supplement Schafer	
4 Excellent pulmonary ventilation	
5 Performed immediately	
6 No apparatus required	
7 Requires only one rescuer	
8 No additional possibilities of trauma	

A number of articles have been published in recent years on the significance of maintaining and promoting the circulation during the administration of artificial respiration[24] It is certainly true that the maintenance of a continuous positive pressure in the lungs above 14 mm. of mercury (8 inches [20 cm] of water) interferes with venous return in a normal person, and it would be deleterious to maintain any appreciable continuous positive pressure in a person requiring resuscitation However, it does not follow that intermittent positive pressure is deletrious to blood flow through the lungs; if this were the case the Drinker respirator would be deleterious, since it is, in effect, an intermittent positive pressure device Whittenberger and Maloney[25] recommend the use of mild positive pressure in a Drinker respirator, alternating with the usual negative as an aid in cases of depressed circulation, although this may not be necessary in the average, young, robust patient with poliomyelitis. It is worth noting, however, that Drinker respirators, even when set for "no positive" (corresponding to negative in a resuscitator) always have a slight positive phase, at least 1 or 2 cm. of water; there is evidence that this is of value, at least to some patients. Further, Motley[26] has demonstrated that any decrease in cardiac output incident to the use of positive pressure is dependent on the type of curve produced and the resulting mean mask pressure. The most physiologic curve is one with a gradual inspiratory rise and a rapid expiratory fall to near atmospheric level, with the expiratory phase exceeding the inspiratory.

Under normal conditions it is known that inspiration produces a slight negative pressure in the large veins of the thorax and that expiration tends to retard the flow.[27] Furthermore, it has been found by radioactive tracer technic in heparinized, recently deceased dogs that the alternate mechanical inflation and deflation of the lungs may cause sufficient movement of blood to spread the radioactive substance throughout the blood vessels[24d] and that ventilation provided by mechanical means is more effective than that provided by manual means[28] There can be no doubt regarding the fact that inflation and deflation of the lungs, particularly when some tendency toward negative or inspiratory pressure is produced in the thorax, will promote a certain amount of blood flow. The amount, however, is not easily measured[24c] This is interesting from a mechanical viewpoint, but is probably of no physiological significance in resuscitation; Ivy and Schwerma[29] clearly demonstrated that there was no statistically significant difference in the effective ness of intermittent positive pressure and alternating positive and negative pressure in the actual resuscitation of dogs from carbon monoxide asphyxia. It may, of course, provide just enough extra circulation of blood in the first few crucial seconds or minutes of resuscitation to make a difference between survival and death. But this means only that the manual method which yields the greatest respiratory excursion, namely, one of the "push and pull" methods which creates positive and negative intrathoracic pressure, would be the method of choice, since a mechanical device is not present during these first few critical minutes. Regarding the choice of a mechanical method for prolonged artificial respiration, a significant difference was not found in the rate of return to normal of the blood pressure reduced to a low level by curare in the experiments of Ivy and Schwerma.[30] Therefore, as long as the method of obtaining pulmonary ventilation is optimally effective and does not lead to the formation of a continuous intrapulmonary positive pressure, the maximum effect possible on the blood flow or circulation is probably being accomplished. It is argued, further, that the Eve method promotes the circulation of blood because of the to and fro movements of the body and the effect of gravity during the rocking,[31] but this has yet to be shown.[19]

In the case of drowning, it has been proposed that first lowering the head to help drain the lungs is indicated. This idea is retained by some despite the generally accepted concept that active artificial respiration should be started immediately and despite Schafer's[6] observation in 1908 that little or no water was found in the lungs after fresh water drowning. The Gettler test,[32] published in 1921, is based on the fact that in postmortem submersion the chloride content of the blood is equal in the right and left sides of the heart whereas it is higher in the right side in fresh water drowning and higher in the left side in salt water drowning, showing that water and electrolytes move violently in a drowning person or animal.[33] In fresh water, the water is rapidly absorbed into the blood. In sea water, water and protein are drawn from the blood into the alveoli and bronchi as in pulmonary edema. This, of course, conforms with the well documented observation that only small quantities of fluid drain from the lungs during inversion after drowning.[34] Maintaining the body in a slightly inclined head-down position during artificial respiration is probably advisable to allow drainage of any fluids that do collect and to combat shock.

Swann,[33c] because he believes that "small amounts" of water may block the airways, has suggested an attempt at drainage before resuscitation. This suggestion is contrary to the accepted dictum that artificial respiration should be given immediately, and it does not conform to our realistic experience. In the presence of massive pulmonary edema in corpses, air exchange by any method is inadequate, and as found in studies by Freeman and Ivy[35] on phosgene poisoning no method of artificial respiration will save life. But, in the presence of moderate pulmonary edema, artificial respiration, though air exchange is reduced, will provide ventilation immediately and during the stage that is crucial for the resuscitation of the heart. Furthermore, our data show that in such cases one of the "push and pull" methods of manual artificial respiration is just as effective in accomplishing pulmonary ventilation as the mechanical resuscitators operating at a maximum mask pressure of 14 mm. of mercury. Operation at a higher pressure is not indicated for routine use or by other than medical personnel, because of the possible danger of interstitial pulmonary emphysema.

Differences of opinion regarding a question that may affect survival can be dealt with only by survival experiments in which a sufficient number of cases are used to give significance to any difference found. Unfortunately this question cannot be determined on the dog drowned to an arbitrary end point in fresh water, because in the dog that absorbs a lethal amount of water into the pulmonary blood acute ventricular fibrillation[36] develops and the dog dies regardless of any resuscitation procedure. Regardless of the end point at which resuscitation is started, all resuscitation procedures save the same number of dogs.[37] Whether this holds for man is not known. It does not hold for fresh water drowning of cats, rabbits or monkeys, in some of which there may develop ventricular fibrillation.[36e]

Cot[38] reports that 10 to 15 per cent of deaths from drowning are due to what he calls "white" asphyxia; the remainder are what he calls "blue" asphyxia and are due to obstruction with water and mucus. The former deaths, he explains, are due to syncope with little or no water in the lungs, and Banting[36c] thought that some deaths were due to spasm of the glottis. In fresh water drowning there need be no equivocation as to whether spasm of the glottis occurred early and caused death, because an examination of the blood for hemolysis and chloride would settle the point.

It would be important to settle the question of whether spasm of the glottis does occur in drowning in man and persists under deep asphyxiation. We know that an asphyxial death may be produced reflexly in certain aquatic animals by submerging of the nostrils. However, reflexly induced spasm of striated muscle does not persist in deep anesthesia or asphyxia or to the point of death.

SUMMARY AND CONCLUSIONS

1. The relative efficiency, as regards the minute volume of pulmonary ventilation, of the manual and mechanical methods for administering artificial respiration for resuscitation was determined on 109 warm corpses within one hour after death and before the onset of rigor mortis and on nine normal subjects with voluntarily suspended respiration after hyperventilation.

2. The manual methods in which the subject lies prone or supine and which utilize both a "push and pull" principle provide approximately twice the minute volume of ventilation obtained with those which utilize only a "push" or a "pull" principle. However, the supine position was found to result in respiratory obstruction in one-half the cases. The "push" or "pull" methods alone did not ventilate in one fourth of the warm corpses.

3. The Nielsen method used in the Scandinavian countries is more effective than the Schafer method. The former is a "push and pull" method and the latter a "push" method.

4. Lifting the hips (Emerson) 4 inches (10 cm.) with the subject prone, a "pull" method, has been found by us to be even more effective than the Schafer method.

5. When the hip-lifting maneuver (Emerson method) is added to the lower chest pressure maneuver (Schafer method) to yield a "push and pull" method (Schafer-Emerson-Ivy method), we find that it is as effective as the Nielsen method or the Schafer-Nielsen-Drinker method.

6. Thus, those who now are indoctrinated with the Schafer prone presssure method can double the ventilating efficiency of the method by lifting the hips 4 inches 12 times each minute, alternating with the push on the lower part of the chest. Lifting the hips is fatiguing and, after the crucial first several minutes, may be employed after every second or third "push" on the lower part of the chest. The newer hip roll-prone pressure method is much easier to perform than the hip lift-prone pressure method and can be executed for long periods of time. The Nielsen method is less fatiguing to perform than the Schafer-Emerson-Ivy method.

7. Intermittent positive (+ 14.7 mm. of mercury) pressure devices and alternating positive (+ 14 mm. of mercury) and negative (— 9 mm. of mercury) pressure resuscitators provide safe, adequate exchange. These machines will signal when obstruction occurs, although inadequate ventilation or obstruction of the airway has not been observed with mechanical respiration.

8. Except for the armamentarium of the anesthetist and the fire, police and rescue emergency crew, all mechanical devices must always be considered as adjuncts and not substitutes for manual method, preferably of the "push and pull' type. The mechanical resuscitator operating at a maximal mask pressure of + 14 mm. of mercury is no more effective than a properly performed "push and pull" manual method. The properly employed mechanical resuscitator requires less skill than a properly executed "push and pull" manual method, is not fatiguing and can furnish 100 per cent oxygen; herein lie the most important advantages of a good mechanical resuscitator. There are other advantages, however. Since a resuscitator need be applied only once to a patient's face, it can be employed where physical manipulation of the body is impossible or would be harmful, as during major surgical procedures, in accident cases with extensive burns, broken vertebrae, ribs or arms, for victims trapped under debris of excavations or overturned vehicles and during transportation to a hospital. Some resuscitators signal when the airway is obstructed and provide an aspirator.

9. If a method of resuscitation provides optimal pulmonary ventilation without producing a continuous intrapulmonary positive pressure, the concern regarding the relation of the method to the promotion or maintenance of the circulation should be secondary. Any effective movement of blood produced will probably be proportional to the effective manual or mechanical intrapulmonary pressure alteration produced.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following report.

R. T. Stormont, M.D., *Secretary.*

POTENCY OF HEPARIN SODIUM

Heparin sodium, widely employed as a potent anticoagulant for the treatment of intravascular clotting, received official status in the U. S. Pharmacopeia XIV, Nov. 1, 1950. Because the drug is not a pure homogeneous substance and must be assayed by biologic methods, the Pharmacopeia has adopted a standard of potency which it requires to be expressed in terms of a heparin unit rather than in terms of weight as currently appears in the labeling for commercially available products. One U.S.P. heparin unit is approximately the quantity of heparin sodium required to maintain fluidity in 1 cc. of plasma prepared according to the directions of the U.S.P. assay for heparin sodium.

The U.S.P. standard provides for a minimum potency of 100 U.S.P. heparin units per milligram but does not limit potency above this equivalent, provided such highly purified products are labeled in terms of units. Therefore, products with greater potency than the minimum retain U.S.P. status and are not construed to be superior to preparations having the official minimum potency.

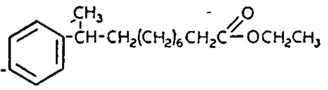
The Council will henceforth require manufacturers of accepted products to indicate potency in terms of U.S.P. units, until such time as a sufficient degree of purification has been achieved to permit assay by chemical methods. Because dosage is still subject to control by clinical tests of the clotting or coagulation time, little difficulty should be experienced in the use of more potent (purified) preparations, as long as the heparin unit rather than weight is used as a basis for determination of the initial and subsequent dosage of the drug. It is hoped that eventually heparin may be sufficiently purified to permit declaration of potency in terms of weight rather than units, in accordance with the current practice for all drugs which can be accurately assayed by chemical methods.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

R. T. Stormont, M.D., *Secretary.*

ETHYL IODOPHENYLUNDECYLATE.—Pantopaque (Lafayette Pharmacal Inc.)—$C_{19}H_{29}IO_2$—M.W. 416.34.—A mixture of the κ and ω isomers of ethyl iodophenylundecylate, which is of quite uniform, but unknown, proportions. The principal isomer is thought to be the κ, whose structural formula may be represented as follows:



Actions and Uses.—Ethyl iodophenylundecylate is an absorbable iodized fatty acid compound of low viscosity designed especially for myelography. It is particularly useful for study of the lumbar region. Intraperitoneal or oral administration in lower animals is moderately toxic, but no toxic phenomena have been observed with massive doses injected intrathecally in higher animals. It is absorbed from the peritoneal cavity of experimental animals in about six weeks and from the subarachnoid space of dogs in about 15 months. In humans, intrathecal injection of 2 to 5 cc. is well tolerated even when the agent is left in the spinal canal. When the bulk of the injected material is removed, the remainder is usually absorbed within two months. When none is removed, absorption proceeds at a variable rate depending on conditions within the spinal canal, sometimes requiring several years.

The incidence and severity of side effects following myelography with aspiration of ethyl iodophenylundecylate is only slightly greater than with ordinary lumbar puncture. In 10 to 30 per cent of patients there may be transient elevation in temperature and increase of symptoms referable to a back condition. The agent should not be employed when lumbar puncture is contraindicated, and to avoid subdural and extra-arachnoid extravasation it should not be used within 10 days of a previous lumbar puncture. It should not be employed as a contrast medium for other body cavities, because the limitations and contraindications for such use are not known.

Dosage.—Ethyl iodophenylundecylate is injected intrathecally by lumbar puncture technic; the 2 to 5 cc. dose is usually injected between the third and fourth lumbar segments. Care should be exercised to ascertain that the needle point is in the subarachnoid space. The injection should be made slowly to detect unusual resistance from obstruction. The needle with adapter is left in place during myelography to implement removal of the agent when the examination is completed. The agent is removed by aspiration in conjunction with fluoroscopic visualization.

Tests and Standards.—

Physical Properties: Ethyl iodophenylundecylate is a colorless to pale yellow, odorless, viscous liquid. The color darkens on long exposure to air. The specific gravity (20/20) is between 1.240 and 1.263. The refractive index is between 1.5230 and 1.5280. It is freely soluble in alcohol, benzene, chloroform and ether and very slightly soluble in water.

Identity Tests: Place about 1 ml. of ethyl iodophenylundecylate, 15 ml. of water and 7 Gm. of sodium dichromate in a 50 ml. round-bottom flask. Carefully add 10 ml. of sulfuric acid. Moderate the vigorous reaction which ensues by cooling the flask with tap water. After the reaction has stopped, reflux the mixture for 2 hours. Cool the contents of the flask and pour it into 25 ml. of water. Filter the mixture with suction, wash the precipitate with a little cold water and recrystallize it from 10 ml. of diluted alcohol. The glistening leaflets of *p*-iodobenzoic acid formed melt between 263 and 265 C.

(Saponification Equivalent) Place about 1 Gm. of ethyl iodophenylundecylate, accurately weighed, in a 250 ml. flask. Add exactly 25 ml. of 0.5 *N* alcoholic potassium hydroxide. Reflux the mixture on a steam bath for 1 hour. Cool the mixture, add 25 ml. of water and 15 drops of phenolphthalein T.S., and titrate with 0.5 *N* hydrochloric acid. Calculate the saponification equivalent (S) from the equation:

$$S = \text{mg. of sample} \div [(\text{ml. KOH} \times N) - (\text{ml. HCl} \times N)].$$

The saponification equivalent is not less than 395 nor more than 420.

Purity Tests: Dissolve 1 ml. of ethyl iodophenylundecylate in 10 ml of chloroform in a glass-stoppered cylinder, add 3 drops of phenolphthalein T.S. and 0.3 ml. of 0.1 *N* sodium hydroxide, stopper, and shake the mixture vigorously: the mixture becomes red *(absence of free acids).*

Place 3 ml. of ethyl iodophenylundecylate and 10 ml. of freshly prepared 0.5 *N* potassium iodide in a 25 ml. glass-stoppered cylinder. Add 5 drops of freshly prepared starch T.S., stopper, shake the mixture vigorously for 15 seconds and allow the cylinder to stand: the aqueous layer shows no blue color *(absence of free iodine).*

Ash about 1 Gm. of ethyl iodophenylundecylate, accurately weighed: the amount of residue is not more than 0.1 per cent.

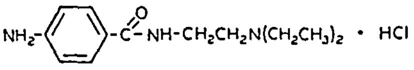
Assay: (Iodine) Place about 0.5 Gm. of ethyl iodophenylundecylate, accurately weighed, 12 Gm. of halogen free sodium peroxide and 0.2 Gm. of lactose in a Parr bomb. Tighten the cap with a wrench and shake the mixture for 45 seconds. Place the bomb in a short length of steel pipe supported vertically over a Bunsen burner. Put a few drops of water on the top of the bomb cap. Light the burner and place it directly under the bomb. (*Caution!* Wear goggles. View the operation by means of a slanting mirror placed at the top of the apparatus.) Heat the bomb until fusion occurs, as shown by the sudden boiling of the water on the bomb cap (about 45 seconds). Cool the bomb in air for 5 minutes, then plunge it into cold water in a metal vessel. Rinse the bomb with water, remove the cap and place the bomb cup in 300 ml. of cold water (*Caution!* keep the mouth of the cup pointed away from you). After the fusion melt is completely dissolved, remove the cup and rinse it with a little cold water. Add the rinsings to the solution. Cool the solution to 10 C. and carefully acidify it to congo red paper with 50 ml. of 1:1 nitric acid. Finally add about 0.5 Gm. of sodium bisulfite dissolved in 10 ml. of water. Heat the solution to boiling, filter it through a tight filter paper, wash the paper thoroughly and add the washings to the solution. Very slowly and with stirring add an excess of 0.1 *N* silver nitrate. Stir to coagulate the precipitate and filter the mixture through a tared Gooch crucible. Wash the precipitate with 300 ml. of water, dry at 105 C. for one hour, cool and weigh. Each Gm. of silver iodide formed is equivalent to 0.5405 Gm. of iodine. The amount of iodine present is not less than 29.0 nor more than 30.5 per cent, equivalent to not less than 95 nor more than 100 per cent of ethyl iodophenylundecylate.

Lafayette Pharmacal Inc., Lafayette, Ind.

Pantopaque: 3 cc. ampuls: An undiluted liquid, ethyl iodophenylundecylate, containing 30.5 per cent iodine in organic combination.

U. S. trademark 401,476. Patent 2,348,231.

PROCAINE AMIDE HYDROCHLORIDE.—Pronestyl Hydrochloride (E. R. Squibb and Sons).—$C_{13}H_{21}ON \cdot HCl$.—M.W. 271.79.—*p*-Amino-N-(2-diethylaminoethyl) benzamide hydrochloride.—The structural formula of procaine amide hydrochloride may be represented as follows:



Actions and Uses.—Procaine amide hydrochloride, like procaine hydrochloride, depresses the irritability of the ventricular muscle. Unlike the latter, the amide is only partially hydrolyzed by plasma esterase to *p*-aminobenzoic acid and diethylaminoethanol, so that its effect is more prolonged. Procaine amide is tolerated in larger intravenous doses than is procaine; on a weight basis, the amide is about one-half to two-thirds less toxic. It differs from procaine also in that it does not produce significant central stimulatory effects. The action occurs almost immediately after intravenous administration and the plasma level declines about 10 to 15 per cent per hour; after oral administration therapeutic levels are attained within 30 minutes to one hour. Plasma levels and urinary excretion rates following oral administration are comparable to those following intravenous injection, indicating almost complete absorption of the drug by the gastrointestinal tract. About 60 per cent is excreted unchanged; some is probably hydrolyzed as indicated above; the fate of the remainder is unknown.

Procaine amide hydrochloride is useful for the treatment of ventricular arrhythmias and extrasystoles occurring either in cardiac diseases or during general anesthesia. When administered intravenously the drug produces a hypotensive effect which is less severe than that with procaine; this effect is partially due to vasodilatation. Hypotensive reactions may be precipitous and clinical judgment is required to determine whether it is necessary to administer vasoconstrictor agents or to discontinue therapy. Epinephrine is likely to aggravate an existing arrhythmia and is therefore generally contraindicated during cyclopropane anesthesia. Until more conclusive evidence becomes available procaine amide hydrochloride is not recommended for the prevention of cardiac arrhythmias, anticipated in either conscious or unconscious subjects.

Dosage.—In conscious patients: For the treatment of ventricular tachycardia, 1 Gm. orally, followed by 0.5 to 1 Gm. every four to six hours as indicated. For the treatment of runs of ventricular extrasystoles, 0.5 Gm. orally every four to six hours as indicated. During anesthesia: 0.1 to 1.0 Gm. (1 to 10 cc. of a solution containing 100 mg. per cc.) intravenously.

Occasional transient electrocardiographic changes resembling those of quinidine intoxication have been observed with procaine amide hydrochloride and should be interpreted by a cardiologist. Intravenous injection is subject to the danger of hypotensive action; oral administration is not

Tests and Standards.—

Physical Properties. Procaine amide hydrochloride is a white to tan, odorless, crystalline solid. It melts between 165 and 169 C. It is very soluble in water, soluble in alcohol, slightly soluble in chloroform, and very slightly soluble in benzene and ether.

Identity Tests. Dissolve about 1 Gm. of procaine amide hydrochloride in 10 ml. of water and add 10 ml. of sodium hydroxide T.S. Extract the mixture twice with 10 ml. of a 1:1 mixture of ether and benzene. Dry the combined extracts over anhydrous calcium sulfate for 30 minutes. Decant the solution into a small flask, add 5 ml. of dry pyridine and add dropwise 1 ml. of benzoyl chloride. Warm the mixture on a steam bath for 30 minutes and pour it into 100 ml. of sodium hydroxide T.S. Separate the organic layer and wash it with 20 ml. of water. Cool the solution to about 10 C., whereupon a crystalline solid separates. Filter the mixture with suction and recrystallize the solid from 20 ml. of diluted alcohol. Dry the solid at 105 C. for one hour: the procaine amide benzoate formed melts between 180 and 187 C.

Prepare a 0.0005 per cent solution of procaine amide hydrochloride and measure the optical density spectrophotometrically in the range 2,500-3,000 A. A maximum occurs at 2,780 A (*distinction from procaine hydrochloride which has a maximum at 2,880 A*).

Purity Tests. Dissolve the sulfated ash, prepared as described in the last paragraph in this section, in 23 ml. of water, add 2 ml. of diluted acetic acid and test for heavy metals by the method of *U.S.P. XIV*, page 717: the amount of heavy metals present is not more than 20 p.p.m.

Dry about 1 Gm. of procaine amide hydrochloride, accurately weighed, at 105 C. for four hours: the loss in weight is not more than 0.2 per cent.

Char about 1 Gm. of procaine amide hydrochloride, accurately weighed. Cool the residue, add a few drops of sulfuric acid and ignite: the amount of residue is not more than 0.1 per cent.

Assay. (Nitrogen) Accurately weigh about 1 Gm. of procaine amide hydrochloride and transfer it to a 500 ml. Kjeldahl flask. Determine the nitrogen content as directed in *U.S.P. XII*, page 740. Each ml. of 0.5 *N* acid consumed is equivalent to 0.007004 Gm. of nitrogen. The amount of nitrogen present is not less than 15.1 nor more than 15.8 per cent, equivalent to not less than 97.5 nor more than 102.5 per cent of procaine amide hydrochloride.

Dosage Forms of Procaine Amide Hydrochloride

Capsules. *Identity Tests.* The contents of the capsules respond to the identity tests in the monograph for Procaine Amide Hydrochloride.

Assay. (Nitrogen) Accurately weigh an amount of powder equivalent to about 1 Gm. of procaine amide hydrochloride and determine the nitrogen as described in *U.S.P. XIV*, page 740. Each ml. of 0.5 *N* acid consumed is equivalent to 0.007004 Gm. of nitrogen. The amount of nitrogen present is not less than 14.7 nor more than 16.2 per cent, equivalent to not less than 95.0 nor more than 105.0 per cent of the labeled amount of procaine amide hydrochloride.

Solution (10 per cent Sterile). *Physical Properties.* Procaine amide hydrochloride sterile solution is a clear, water white liquid. The *pH* is about 5.5.

Identity Tests: Procaine amide hydrochloride solution responds to the identity tests in the monograph for Procaine Amide Hydrochloride.

Assay. (Nitrogen) Accurately measure a volume of solution containing about 1 Gm. of procaine amide hydrochloride and transfer it to a 500 ml. Kjeldahl flask. Determine the nitrogen content by the method of *U.S.P. XII*, page 740. Each ml. of 0.5 *N* acid consumed is equivalent to 0.007004 Gm. of nitrogen. The amount of nitrogen present is not less than 14.3 nor more than 16.6 per cent, equivalent to not less than 92.5 nor more than 107.5 per cent of the labeled amount of procaine amide hydrochloride.

E. R. Squibb and Sons, New York

Capsules Pronestyl Hydrochloride: 0.25 Gm.

Solution Pronestyl Hydrochloride: 10 cc. vials: A solution containing 100 mg. of procaine amide hydrochloride in each cc. Preserved with 0.9 per cent benzyl alcohol and 0.09 per cent sodium bisulfite.

DIHYROSTREPTOMYCIN-U.S.P. (See The Journal, July 8, 1950, page 896).

The following dosage form has been accepted:

Premo Pharmaceutical Laboratories, Inc., South Hackensack, N. J.

Dihydrostreptomycin Sulfate: 50 cc. vials. Dihydrostreptomycin sulfate powder equivalent in activity to 5 Gm. of dihydrostreptomycin base.

DIA-MER-SULFONAMIDES (See New and Nonofficial Remedies 1950, page 126, Sulfadiazine-Sulfamerazine Combined).

The following dosage forms have been accepted:

Casimir Funk Laboratories, New York

Syrup Duo-Sulfanyl with Sodium Citrate: 118.3 cc., 473 cc. and 3.78 liter bottles. A suspension containing 50 mg. each of sulfadiazine and sulfamerazine and 0.1 Gm. of sodium citrate in each cc.

E. S. Miller Laboratories, Inc., Los Angeles

Tablets Sul-Di-Mill with Sodium Bicarbonate: Each tablet contains 0.22 Gm. each of sulfadiazine and sulfamerazine and 0.3 Gm. sodium bicarbonate.

ANTICOAGULANTS AS A CAUSE OF HEMORRHAGE

Physicians using anticoagulants must beware of the risk of hemorrhage. Major hemorrhage occurred in 1.9 per cent of 9,609 patients given dicumarol,® according to the literature. Data obtained from a questionnaire[1] answered by 136 physicians experienced in the use of dicumarol® and heparin indicate that major hemorrhage occurred in 2 per cent of about 15,500 patients treated. The chief site of major hemorrhage was the urinary tract. Gross hematuria occurred in 93 cases recorded in the questionnaire, but in no instance was it the cause of death although hematuria was associated with fatal bleeding in other sites in three cases. Hematuria was not followed by residual renal impairment Most other instances of major bleeding were associated with pathological lesions in the gastrointestinal tract or lungs or were in postoperative sites. In the Report of the Committee for the Evaluation of Anticoagulants in the Treatment of Coronary Thrombosis with Myocardial Infarction[2] hemorrhagic complications occurred in 54 patients, or 9 per cent of the treated group; in half the condition was mildly severe. An additional 6 per cent of the treated group had hemorrhage not due to anticoagulants, while in the "control" untreated group hemorrhage occurred in 6 per cent. Hemopericardium was found in 11 of the treated and only four of the control group.

Eighty deaths have been attributed to hemorrhage following the use of anticoagulants. Duff and Shull[3] found 21 deaths in the literature due to dicumarol® and added two others; in addition they mentioned five other deaths due to heparin or dicumarol.® Subsequent reports of four deaths have appeared.[4] Nichol[1] has added 35 previously unpublished hemorrhagic deaths due to heparin or dicumarol® brought to light by a questionnaire, showing that many such catastrophies do not find their way into print. Cohen[5] recently collected from the literature 12 deaths in patients with subacute bacterial endocarditis from cerebral hemorrhage in combined heparin-antibiotic therapy, and added two more In the report of Duff and Shull[3] and in Nichol's article, 11 similar deaths were included, making 25 recorded deaths from cerebral hemorrhage in cases of subacute bacterial endocarditis treated with combined antibiotic and anticoagulant therapy. These deaths occurred prior to 1945; since that time it has been generally agreed that anticoagulants have no place in the treatment of this condition, although cerebral hemorrhage does occur without anticoagulant therapy in subacute bacterial endocarditis due to rupture of a mycotic aneurysm or hemorrhagic cerebral infarction. Death occurred in 55 patients who were being treated for conditions other than subacute bacterial endocarditis; 52 of these deaths occurred in the United States.

Fatal hemorrhage was generalized in 13 patients receiving dicumarol®; this was often due to complete lack of laboratory control. Nine deaths occurred in patients with carcinomatosis for whom the outlook was poor. That three patients with dissecting aortic aneurysm were treated on the assumption myocardial infarction was present points to the need to rule out this condition before anticoagulants are used. Hemopericardium was found without ventricular rupture in three other cardiac cases. Five deaths resulted primarily from the act of performing lumbar sympathetic blocks when anticoagulants were in force, although hemorrhage was found elsewhere in three cases. The use of spinal anesthesia in one patient and the performing of dorsolumbar sympathectomy in another, during the concomitant use of anticoagulants, accounted for two deaths. Fatal cerebral hemorrhage developed in 10 patients, half of whom had hypertension, but whether hypertension increases the risk of cerebral hemorrhage during anticoagulant therapy cannot be stated. Of 78 cases of long term dicumarol® therapy[6] hypertension was present in 37 per cent, yet cerebral hemorrhage developed in only one hypertensive patient.

Clinicians experienced in the use of anticoagulants agree there is less risk of hemorrhage with heparin than with dicumarol.® The Lee-White test of clotting time to control heparin therapy can be done by the average technician. Protamine sulfate, given intravenously, helps to correct the coagulation defect following heparinization. Unless the available laboratory is well versed in the pitfalls of the prothrombin determination, dicumarol® should not be used, for lack of reliable laboratory facilities to measure prothrombin time is the most important of all contraindications to its use. The vagaries of the Quick test of prothrombin time or the Link-Shapiro modification of this test necessitate special knowledge of the technic. Bleeding induced by dicumarol® is usually controlled by adequate amounts of water-soluble vitamin K (menadione bisulfite) or K oxide. Transfusions of blood and plasma are of value after hemorrhage due to either heparin or dicumarol.®

False confidence is inspired in the clinician if the laboratory renders the prothrombin time in percentage of normal. To follow adequately the prothrombin response to dicumarol® the clinician should know the normal range of the test as done by the available laboratory, and he should adjust the dicumarol® dosage in an attempt to maintain the prothrombin time between two and two and a half times the average normal, expressed in seconds obtained by identical technic with the same thromboplastin, in which event the percentage of prothrombin activity will fall between 10 and 30 per cent, a safe yet effective bracket. Hemorrhage rarely occurs until the prothrombin activity is depressed to 5 per cent, unless some pathologic lesion is present in the kidney, gastrointestinal tract, lungs or brain.

The incidence of hemorrhage following the use of anticoagulants depends to some extent on the philosophy of the clinician, who may be inclined to "push" the dosage in the belief that it is more desirable to assure patients with cardiovascular disease full protection against thromboembolic complications, thus running some risk of hemorrhage, rather than to use a dose carrying with it so little chance of hemorrhage that it might fail to inhibit intravascular clotting. Physicians must make it their responsibility to see that prothrombin or clotting studies are accurately performed, as it now becomes plain that deaths from anticoagulants, other than in persons taking dicumarol® without medical supervision, ensues chiefly from poor laboratory control, while overdosage by the physician, concomitant ill advised surgical procedures and diagnostic error account for the remainder of anticoagulant-induced fatalities.

EPIDEMIC PLEURODYNIA

During August and September of 1947, 114 patients with "epidemic pleurodynia" were admitted to one Boston hospital.[1] The disease was characterized by fever and pleuritic pain, often accompanied by headache, abdominal pain and stiffness of the back and neck. From stored throat washings from typical cases Weller [2] and associates of Harvard University and Tufts College have recently isolated a virus antigenically related to the "Connecticut 5" virus previously isolated by Melnick [3] from a case of "nonparalytic poliomyelitis."

After intracerebral inoculation of 100 LD_{50} of the new virus into newborn mice, death usually takes place in three to six days. Necropsy usually shows two to three drops of light yellow fluid in the abdominal cavity, diffuse hepatitis and occasional pancreatitis. Older mice are more resistant, and one rhesus monkey showed no signs of infection by this virus.

Stored serums from patients during the first three or four days of the disease had no demonstrable antibodies against this virus. Serums collected from the same patients about 10 days later completely neutralized the virus. While tests with hyperimmune mouse serums showed an identity of the new virus with Melnick's "Connecticut 5" virus, no antigenic relation was demonstrated with certain other members of the Coxsackie group of viruses.

MIDCENTURY WHITE HOUSE CONFERENCE ON CHILDREN AND YOUTH

The actions taken at the recent Midcentury White House Conference, December 3-7, the fifth to be called at decennial intervals, will take root in the states and their communities to mold a new understanding of the influences that affect the healthy personality development of our children and youth. After 35 work groups, 30 panel discussions and seven general sessions, the 6,000 conferees adopted 201 statements of findings developed by the work groups, 66 recommendations promulgated by the work groups and screened through a special recommendations committee, a Pledge to Children, similar to the Children's Charter of 1930, and a Resolution on a Follow-up Program. Comparatively little of this material is concerned with medical care or even with health service as such. This little will be acceptable to most physicians and is not out of line with medical society policy. Most of the recommendations are concerned with the preservice and in-service training of professional personnel in all fields dealing with the developmental phases of childhood, parent education, agency responsibility, economics, education, social work, recreation, religion, the problems associated with war and the problems of minority groups.

The most important recommendations concern the continuing character of the program initiated by this conference. It has been recommended "that community groups and community leaders reexamine their attitude and procedures and make appropriate adaptations and changes . . . that to insure proper assessment, creative planning and appropriate action with respect to meeting the needs of children and youth, communities develop broad community interests, obtain the broadest possible community sponsorship, obtain necessary technical assistance, initiate and organize studies and gather facts and interpret the facts and inform the community of their significance." It is stressed that "people as individuals and as groups should be helped to help themselves . . . that greater emphasis be placed by the various professions on bringing the parents into participation in thinking and planning with and for children . . . and that citizen advisory boards and similar groups representative of the community be established for public services as well as private and that every effort be made to enable and secure participation by a cross section of the citizenry."

Before another year has passed, most states will have had a "little White House Conference" under the leadership of the state delegation that has just participated in the midcentury conference. All state agencies involved in the problems of children and youth will be invited to participate. Here the practicing physician, his local and state medical society, his health department and his voluntary health agencies can do yeoman service for the children and youth in his state and community. Here the physician has the privilege and opportunity to make constructive contributions to the healthy personality development of children and youth. Though a national conference may turn fine phrases and make broad recommendations, it is the citizen in a community who gets the job done, and the physician is such a citizen.

CONFERENCE COMMITTEE ON GRADUATE TRAINING IN SURGERY

In this issue is an announcement (page 1503) of the establishment of the Conference Committee on Graduate Training in Surgery, representing the Council on Medical Education and Hospitals of the American Medical Association, the American Board of Surgery and the American College of Surgeons. The establishment of the Conference Committee on Graduate Training in Surgery is the result of negotiations conducted over a two year period by the Board of Trustees, the Board of Regents of the College of Surgeons and the American Board of Surgery. At the Annual Session in San Francisco, the Board of Trustees approved the principles under which the Conference Committee was to be organized. Since these principles had previously been approved by the governing bodies of the other two organizations, the Committee received official status at that time.

The purposes of the Committee are to formulate uniform standards for residency training in surgery, to sponsor a single inspection service for hospitals offering such training and to approve and publish a list of acceptable residency programs. The first such list, approved by all three participating organizations, appears in this issue.

The uniform set of standards for evaluation of residency programs in surgery has already been approved by the three agencies, as published in the June 1950 Revisions of the Essentials of Approved Residencies and Fellowships. Since the establishment of the Conference Committee, field surveys of hospitals applying for approval of residency programs in surgery have been made by representatives of the Council's staff. This collaborative effort, eliminating as it does differing requirements for approval, as well as a duplication of work in inspection of hospitals conducting programs in surgery, on the part of the three agencies concerned should be generally welcomed. It is to be hoped that the pattern established in approving residencies in this specialty will be adopted in other areas of residency training, with similar beneficial results.

TULAREMIA PROPHYLAXIS

Reports of tularemia among laboratory workers have indicated a high incidence of infection due to Pasteurella tularensis approaching 100 per cent.[1] To avoid this danger prophylactic vaccination has been suggested.[2] The efficiency of such vaccination has been tested by Foshay[3] and associates of Camp Detrick, Maryland.

Two vaccines were tested: (*a*) a phenolized broth culture of P. tularensis and (*b*) an acetone-extracted vaccine of the same organism. In a preliminary test 0.5 cc. of one vaccine was given subcutaneously to 15 unselected subjects. Three suffered severe systemic reactions necessitating hospitalization. Subsequent study of serums drawn from them before vaccination showed that all three had circulating agglutinins for P. tularensis. All had been exposed to possible tularemia infection in the past.

In order to prevent additional severe reactions, prevaccination skin reactions and agglutinin titers were determined for each prospective subject. Those with positive skin reactions and high agglutinin titers were excluded. Eight hundred and nine subjects with negative reactions were then given one or more prophylactic injections. The toxic effects were no more than would be anticipated from the use of typhoid vaccine. Among those vacinated were 163 laboratory workers. Of these, 72 handled cultures or performed necropsies on infected animals. The remaining 91 washed glassware or did janitor service or maintenance repair.

Of the 72 vaccinated subjects, with maximum daily exposure, 22 (30.6 per cent) subsequently acquired laboratory infections with P. tularensis. This is approximately one-third the expected incidence among unvaccinated laboratory personnel under similar conditions of exposure. Among the 91 with less exposure only one acquired primary tularemia. The authors conclude from these data that, with precautions to exclude hypersensitive persons, prophylactic vaccination should be carried out on all those exposed to tularemia as an occupational or recreational hazard.

ORGANIZATION SECTION

ABSTRACT OF PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION AT THE CLINICAL SESSION IN CLEVELAND, OHIO, DECEMBER 5-8, 1950

The actions of the House of Delegates at the Cleveland Session are herewith abstracted so that the readers may have this information in digest form. The complete proceedings will be made available, as in the past, in a booklet, which will be sent to all the members of the House of Delegates and officers of the American Medical Association by the Secretary. This booklet will not be available for several weeks.—Ed.

General Practitioner of the Year

The House of Delegates had before it nominations of Dr. Jim Camp, Pecos, Texas, Dr. Dean Sherwood Luce, Canton, Mass., and Dr. John William Strange, Loogootee, Ind. On a second ballot, the House elected Dr. Dean Sherwood Luce of Canton, Mass., the General Practitioner of the year.

Address of Speaker

The Speaker presented the following address:

Mr. Speaker and Members of the House of Delegates of the American Medical Association:

Slightly less than six months ago this House met at San Francisco. Perhaps no previous legislative session in the history of this body approached either the volume or variety of significant actions taken. The few months that have elapsed since June 30 last have also seen evidences of the trend away from the radical road toward socialism and the dissolution of our liberties and the American Way of Life. But, Gentlemen, the victory is by no means won. I must again, as previously, warn you that while we have won signal victories in stemming frontal attack, we still face more or less insidious flank movements which, if successful, can and may prepare the way for ultimate regimentation and enslavement.

The House of Delegates, in the name of the American physicians for whom it speaks and acts, bears the full responsibility for defending the American people against any and all threats to the provision of the highest quality of service Medicine can provide.

The reports of the Board of Trustees, officers and councils as already published, and probably augmented by supplementary reports are ample evidence of the magnitude of the problems with which organized medicine most concerns itself. It is obvious to me that in recent years each session of this House finds itself facing more and increasingly complex problems. This will be no exception. In order, then, to give your fullest and best efforts at reaching sound solutions with the limited time available, consideration must be given to conservation of time, energy and orderly procedure.

For the benefit of those delegates serving for the first time and to refresh the memories of others, let me review briefly some details of procedure. May I do this categorically, for brevity's sake.

1. Have all formal resolutions typed in proper form, with adequate copies. A staff of typists is at your service.

2. When addressing the chair or House, announce clearly your name, the state or territorial association, the scientific section or government service you represent.

3. In presenting resolutions, please omit reading the so-called "whereases," but read carefully the resolutions to be acted on. The reasons and arguments for the resolutions can and must be read in the reference committees.

4. Attend the reference committee hearings to plead your cause and to assist the committee in reaching conclusions. Full and exhaustive discussions should take place in the reference committee rooms. It is as much the delegates' responsibility to attend reference committee hearings as it is for them to be seated in the House during its deliberations.

May I take this opportunity to express to the House of Delegates my personal satisfaction at having my right bower, your Vice Speaker, Dr. Reuling, back with me.

I am grieved to announce to you that my predecessor, Dr. Roy Fouts, is reported desperately ill, and I hope the House will extend to him our sincere wishes for recovery.

It is imperative that the business of this session be concluded by noon on Thursday. This is in order to permit a joint session of the House, the Coordinating Committee for the National Education Campaign and the "Committee of 53" for the purpose of receiving a communication which is of profound and far reaching significance.

The Speaker then read the names of the members of the Reference Committees.

Report of Reference Committee on Reports of Officers

The Reference Committee on Reports of Officers presented the following report, which was adopted:

Your committee wishes to commend the Speaker for the conciseness and accuracy of his address, the contents of which met with the full accord of the reference committee. It finds itself in complete agreement with the Speaker's statement to the effect that we must continue our fight against compulsory health insurance unabated.

It wishes to commend the Speaker further for his clear-cut instructions to the delegates giving them the details of the procedure to be followed so that there will be a unanimity in the work to be done.

Your committee cannot dismiss the Address of the Speaker without taking this opportunity to commend him highly for his efficiency, his impartiality, his fairness and his patience in conducting the affairs of this body.

Address of President, Dr. Elmer L. Henderson

President Elmer L. Henderson presented an address (see Journal of the American Medical Association, Dec. 9, 1950, pages 1268-1269) and the Reference Committee on Reports of Officers, to which it was referred, reported as follows and its report was adopted by the House:

The Address of the President to this House of Delegates delivered on December 5 was in all ways characteristic of the manner in which our leader operates. His report was brief, concise and factual.

Your committee concurs with his statement regarding the value of our advertising campaign which campaign "marked the first time in the history of the United States that any profession, business or industry under government attack has been successful in rallying nationwide advertising support from thousands of unrelated groups, companies and individuals."

It feels that the 65,000 new-won friends of our profession will prove of great benefit to us, and that we can see a direct evidence of some of these benefits in the splendid articles now appearing in the Cleveland papers as well as those contributed by the press associations.

As our President states, the election results last month were "heartening and reassuring to the medical profession." Your committee adds to his its "praise and commendation for all doctors regardless of their party affiliation who as American citizens played their rightful role in public affairs and who fought for their convictions at the polls."

Your committee noted with regret the absence in the President's Address of any reference to the innovation of "The President's Page" in The Journal of the American Medical Association. It feels that this page has the potentiality for great good and that it is an excellent means of direct contact between our President and the individual members of this organization. Your committee is of the opinion that it has wide public relations opportunities and strongly recommends that "The President's Page" be continued.

Report of Secretary

The Reference Committee on Reports of Board of Trustees and Secretary, to which the Report of the Secretary (see THE JOURNAL, Oct. 21, 1950, pages 632-633) was referred, approved this report and was of the opinion that the service rendered by the Secretary should receive an expression of appreciation from the House.

Report of Board of Trustees

The Reference Committee *on Reports of Board of Trustees* and Secretary, to which the Report of the Board of Trustees (THE JOURNAL, Oct. 21, 1950, pages 633-663) was referred with certain exceptions, took actions as follows, which were adopted.

The following reports, included in the Report of the Board of Trustees, were not considered by this committee because they were sent to other reference committees by the Speaker: Matter of Free Choice of a Physician; Hospital Standardization; Report of the Washington Office; Report of the Assistant to the Manager, Department of Public Relations; Report of the Council on Industrial Health; Report of the Council on National Emergency Medical Service; Report of the Committee on Legislation; Report of the Committee on Blood Banks, and Report of the Committee on Rural Health.

Matters Referred to the Board of Trustees by the House of Delegates

Your committee approves the action of the Board on matters that had been referred to it and reported on by the Board including Quality of Medical Care in the National Health Program; Resolution on Appropriation for Expenses of Section Delegates; Resolution on Costs of Medical Care; Resolution on Multiplicity of Meetings of Councils of American Medical Association; Resolution on Pilot Survey of Practitioners of So-Called Healing Arts; Resolution on Medical Care of Civilian Employees of Armed Forces; Resolution on Council on Federal Medical Services; Twelve Point Program, and Resolution from Section on Diseases of the Chest on Tuberculosis Among Indians.

The actions of the Board of Trustees on Dues, Entertainment of Foreign Guests, Place of 1952 Clinical Session, Student American Medical Association, Investment Policy, The Journal and Special Journals, Today's Health, Standard Nomenclature of Diseases and Operations, American Medical Directory, Library, Quarterly Cumulative Index Medicus and Report of State Journal Advertising Bureau and the Reports of Council on Pharmacy and Chemistry, Laboratories, Council on Physical Medicine and Rehabilitation and Council on Foods and Nutrition, Report of Bureau of Investigation, Report of Bureau of Legal Medicine and Legislation, Report of Bureau of Health Education, Report of Bureau of Exhibits and the Report of the Bureau of Medical Economic Research were approved by the committee and its report was adopted by the House.

Report of Washington Office

The Speaker referred the Report of the Washington Office in the Report of the Board of Trustees, (see THE JOURNAL, Oct. 21, 1950, pages 637-638) to the Reference Committee on Legislation and Public Relations, which presented the following report which was adopted:

Your committee notes with satisfaction the substantial expansion of this facility and that the many services rendered by this office have been received with interest by the profession. It particularly commends the interesting style used in the Bulletin and Capitol Clinic. It is obvious to your committee that this office has played an important role in reviewing legislation, supplying material to members of Congress, and also arranging for hearings on matters of interest to the medical profession. This activity continues to be of the utmost importance. It is interesting to note that several bills, including the Doctor Draft Law, favored by your Association have been enacted into law and that not a single bill opposed by American medicine has passed.

Report of Assistant to General Manager, Department of Public Relations

The Speaker referred the Report of the Assistant to the General Manager in the Report of the Board of Trustees (see THE JOURNAL, Oct. 21, 1950, pages 638-641) to the Reference Committee on Legislation and Public Relations, which reported as follows and its report was adopted:

In accordance with the expressed policy of the Association, your committee notes that the Department of Public Relations has greatly increased its activities during the past year and particularly would like to point to the establishment of excellent press relations which have included fine coverage of meetings such as the San Francisco Session, the World Medical Association and rural health. The spread of the various news services to even smaller newspapers is commendable. The cultivation of contacts with key organizations has done much to obtain the good will of these groups and this should be further explored.

Report of Council on Industrial Health

The Speaker referred the Report of the Council on Industrial Health in the Report of the Board of Trustees (see THE JOURNAL, Oct. 21, 1950, pages 648-649) to the Reference Committee on Industrial Health, which reported as follows and the report was adopted:

1. Civil Defense: Your committee welcomes the reactivation of the Committee and Consultants on the Industrial Medical Aspects of Civil Defense and urges that this group assume leadership in promoting the four subjects mentioned in this report. This work should go hand in hand with the activities of the Council on National Emergency Medical Service and with all government agencies affected.

2. Public Relations: As was reported in previous recommendations of the House of Delegates, opposition from certain labor leaders seems to be definitely an attempt to squeeze a compromise from the American Medical Association on other broad policies. Your committee recommends the effort to effect a joint committee composed of management, labor and American Medical Association, on health in industry program be continued in spite of setbacks from labor groups.

3. Multiphasic Screening: The Council has presented a seven-point program that is recommended for acceptance by the House of Delegates as a general statement of policy on this subject. Your committee strongly advises that any broad statement of policy of the American Medical Association on any subject be scrutinized thoroughly and be issued only when it would be a strengthening part of our entire program. Here we have a subject that is being pushed by those who believe in continued advance of social security programs by surveys of entire areas, as well as groups in industry. Your committee certainly favors physical examinations of employed groups by family doctors and industrial surgeons, and the use of statistical information obtained for bettering health, accident prevention and plant sanitation. On the other hand, screening by government agencies has developed into a springboard from which chain reactions emanate. The figures from group surveys have been followed by requests for appropriations to institute treatments or further study. This appropriation automatically recognizes and sets up another Social Security sub-group to carry out recommendations founded on this original survey findings. In a case in point, a survey costing thousands dug up six patients. A follow-up appropriation was requested. Your committee recommends that the subject of mass health surveys, either in industry or otherwise, be deleted from this report, as it is not a problem of industry in itself. General health and undiscovered pathology is the background of general health of the nation and should be the business of the family doctors rather than outside group doctors. Your committee recommends that in place of the paragraph deleted, the following be inserted: "Your committee recommends that industrial physicians continue their program of careful examinations of those in industry and the continued referral of those with coincidental disease to insure proper follow-up cure and assignment to suitable occupations of individuals with residual impairment.

4. Corporate Practice: The application of the principles of the Hess report to industrial practice is being well considered by the Bureau of Legal Medicine and Legislation. Its report is not complete at this time.

5. Professional Relations: Your committee compliments the Council on this part of the report, showing as it does the excellent cooperation and understanding that is being used with ancillary groups in industry and industrial health.

6. Industrial Nursing: More time is needed to cooperate with interested groups. The differences in state laws regarding the practice of nursing has made continued study necessary by the Bureau of Legal Medicine and Legislation before a policy acceptable to all concerned can be obtained.

7. First Aid Training, Accident Prevention, Workmen's Compensation: These have been dealt with in an exceedingly satisfactory manner and your committee commends this part of the report.

8. Industrial Health in England: Comments on this were short, and because of the visit of several Council members to England and the direct knowledge obtained your committee recommends that this subject be supplemented by a more detailed report with personal opinions from the Council.

9. Scientific Development and Education: Your committee commends the Council on the work accomplished and urges that the ideas expressed be followed up and the two committees named be activated as soon as possible.

Your committee wishes to call attention to the arduous and intelligent work done by this Council and congratulates the members and secretary on a job well done.

Report of Council on National Emergency Medical Service

The Speaker referred the Report of the Council on National Emergency Medical Service in the Report of the Board of Trustees (see THE JOURNAL, Oct. 21, 1950, pages 649-651) to the Reference Committee on Emergency Medical Service, which reported as follows and the report was adopted:

The committee is in full agreement with the Report of the Council on National Emergency Medical Service. Its concise report covers every essential detail necessary to the implementation of a Civil Defense program and procurement of medical officers for the armed services. In addition and as a further aid to the economical utilization of the limited number of physicians available to the nation at this time, the council has recommended that the American Medical Association urge that reserve medical officers not on active duty be utilized to the fullest extent to complete and execute a single final type physical examination of inductees, recruits and reservists that is acceptable to the armed forces, with point accreditation under public law 510 of the Eightieth Congress. It is understood that steps have already been taken by Secretary of Defense in this regard and that the Secretary of Defense has been commended for his action in the matter by the Board of Trustees.

Your committee feels that civilian defense will be with us for a long time and agrees with the report that the medical profession must exert a forceful, dynamic leadership in the civil defense program of the nation at national, state and local levels. It would therefore make the following recommendations: (1) that each of the state and territorial associations seek adequate representation on civil defense advisory committees at all levels of government; (2) that the American Medical Association request appointment of an advisory committee of civilian physicians in the new Civil Defense Administration; (3) that a copy of the report of the Council on National Emergency Medical Service be sent to secretaries of state and territorial associations and to the chairman of the Emergency Medical Service Committee in each state; (4) that the two remaining constituent associations without an Emergency Medical Service Committee be urged to appoint such a committee without delay. All other constituent associations have such a committee, but many are without a complete program; (5) that the Council on National Emergency Medical Service and the Committee on Blood Banks have some appropriate space in THE JOURNAL, so that information regarding the actions and recommendations of their respective committees be brought to the attention of our members and the various Emergency Medical Service Committees as promptly as possible. Your committee believes this would be a valuable means of keeping all informed of the latest developments in their programs. This recommendation does not imply any criticism of the Editor of THE JOURNAL in relation to publication of news of these matters in the past, but it feels that if the members knew that information relating to civil defense, blood bank and procurement of officers for the armed services was to be placed in some part of THE JOURNAL with a leading heading, it would help in the early dissemination of this information, and (6) that the Council on National Emergency Medical Service urge the state emergency committees in all the constituent organizations to complete their programs without further delay if they have not already done so, and stress the importance of their work in the over-all civil defense program.

Some of the states have already enacted a state civil defense law. Many others will probably do so in the near future and our state medical emergency committees should be active participants in the state civil defense commissions where such laws are enacted.

Dr. Alfred S. Hartwell, delegate from Hawaii, gave to the committee a most excellent booklet on Burn Therapy. It is the most complete treatise on burn therapy that your committee has seen, and it is submitting it to the Council on National Emergency Medical Service.

Report of Committee on Legislation

The Speaker referred the Report of the Committee on Legislation (see THE JOURNAL, Oct. 21, 1950, page 661) to the Reference Committee on Legislation and Public Relations, which reported as follows and the report was adopted:

The work of the Committee on Legislation covers a small section of the Report of the Board of Trustees, but it is obvious that this committee has spent much time in consideration of many bills and the members should be particularly commended for this work. Your committee wishes to note the excellence of the presentation of those who represented the American Medical Association before congressional committees and to state its appreciation of their competent services.

Report of Committee on Rural Health

The Speaker referred the Report of the Committee on Rural Health in the Report of the Board of Trustees (see THE JOURNAL, Oct. 21, 1950, pages 661-662) to the Reference Committee on Hygiene and Public Health, which reported as follows, and the report was adopted:

The committee considers the solution of the rural health problem is gradually being achieved through cooperative community effort. It gives credit to progress made, to the factors which have developed from the deliberations of the four National Rural Health Conferences, the most important being:

1. State and Local Public Health Services for general community hygiene; communicable disease control; public health nursing; well baby conferences and clinics.
2. Utilization of the Hill-Burton Hospital Construction Act in interested areas.
3. Interest of the medical profession and local organizations in provision of scholarships for medical students and nurses who may agree to return to a rural area to practice.
4. Building a better and more productive community and a better place in which to live, through agricultural school extension services.
5. Encouragement by Parent-Teacher Associations of preschool and school health examinations and immunizations; and profiting to a greater extent from the educational programs of voluntary health agencies—tuberculosis, poliomyelitis, cancer, heart and other foundations.
6. Greater participation in voluntary prepaid medical and hospital care plans; in such services offered by many farm groups; and development of plans to include the medically indigent and low income farmer.
7. Combined efforts of all groups in the community, to promote state and county health councils, and implement the activities of county health units in accord with recommendations of the Reference Committee on Hygiene and Public Health in its report at the St. Louis Session in 1948.

More than 750 farm and health leaders participated in the 1950 conferences. The committee plans an annual meeting to expedite the objectives just outlined, with emphasis on the formation of community health councils. The services of a secretary and a field director have widened the scope of activity, the latter having visited 23 states in recent months. Increasing interest has been indicated by the Extension Service, Farm

Bureau, National Milk Producers Association, National Grange and similar groups. A gratifying result has been acceptance of appointment as advisory members of Berry H. Akers, Editor of "The Farmer" and Paul Johnson, Editor of the "Prairie Farmer."

The Reference Committee on Hygiene and Public Health is in full accord with the objectives of the Committee on Rural Health and commends its accomplishments. No specific requests or recommendations requiring action by the House are presented by your committee.

Supplementary Report of Board of Trustees on Recommendation on Resolution on Free Choice of Physicians for Federal Employees

The following recommendation was presented by Dr. Louis H. Bauer, Chairman, Board of Trustees, and referred to the Reference Committee on Industrial Health:

Since the Handbook went to press, a report prepared by the Committee on Consultants on Workmen's Compensation has been received by the Council on Industrial Health. This report is to the effect that in the opinion of the Committee on Consultants the moment is not a propitious one to press for amendments to the Federal Employees' Compensation Act to provide for free choice of physicians, as requested in the resolution presented to the House of Delegates by Dr. J. Stanley Kenney of New York at the Atlantic City Session in June 1949.

Report of Reference Committee on Industrial Health

The reference committee presented the following report, which was adopted:

The resolution on free choice of physicians for federal employees was originally introduced by Dr. J. Stanley Kenney of New York and referred first to the Board of Trustees, then to the Committee on Consultants on Workmen's Compensation of the Council on Industrial Health and finally to your committee.

Your committee does not recommend the acceptance of the report given by the Committee of the Council on Industrial Health, but recommends the adoption of the original resolution by Dr. Kenney, which is as follows:

WHEREAS, It is the custom of the United States Employees Compensation Commission to appoint designated surgeons in all localities where a U. S. Marine Hospital or Veterans Facility is not available for the care and treatment of injured employees; and

WHEREAS, All injured employees are directed to one of these designated surgeons when injured in line of duty; and

WHEREAS, Certain other branches of the federal government, namely, the Veterans Facilities, have recognized the free choice of physician plan in home treatment of veterans; and

WHEREAS, All injured employees in New York state enjoy this privilege under the New York State Compensation Law; now therefore be it

Resolved, That the Board of Trustees of the American Medical Association is hereby requested to seek amendment to the Federal Law on Workmen's Compensation to the effect that all covered federal employees be granted free choice of physician for injuries sustained in line of duty.

Supplementary Report of Board of Trustees on Clinical Sessions

The following Report of the Board of Trustees on Clinical Sessions was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

1953 Clinical Session: Invitations for the 1953 Clinical Session were received from the following cities: Atlantic City, Boston, Los Angeles, Miami, Minneapolis and St. Louis. The Board of Trustees selected St. Louis, but the exact date has not as yet been set.

Date for Denver Session: The first week in December has been selected for the 1952 Clinical Session which is to be held in Denver.

Continuation of Clinical Session: The Board of Trustees would like to have an expression from the House of Delegates as to whether it feels that the clinical sessions of the Association are worth while and should be continued.

Report of Reference Committee on Reports of Board of Trustees and Secretary

The reference committee reported as follows and the report was adopted:

Article 2 of the Constitution of the American Medical Association states "The objects of the Association are to promote the science and art of medicine and the betterment of public health." Your committee heard many witnesses regarding this subject, including officers, members of the Board of Trustees, the Council on Scientific Assembly and others. It is the opinion of your committee that in view of Article 2 of the Constitution, which essentially states that the primary purpose of the American Medical Association is to promote the science of medicine, and after noting the results of a survey made following the St. Louis Clinical Session and the fact that there has been increasing attendance at these sessions, the Clinical Sessions should be continued. It suggests that the Board of Trustees and the Council on Scientific Assembly consult with the officers of the Section on General Practice for advice regarding possible continued improvement in the scientific program. It approves of the action of the Board of Trustees in this supplementary report regarding the 1953 Clinical Session and the date for the Denver Session.

Since it has been brought to the attention of the committee that several delegates at this and previous clinical sessions have arranged transportation home in advance of adjournment of the House of Delegates, your committee hopes that in the future the Board of Trustees will specify the dates when it is anticipated the House will meet so that there can be no misunderstanding on the part of the delegates.

Supplementary Report of Board of Trustees on Hospital Standardization

Dr. Louis H. Bauer, Chairman, Board of Trustees, presented the following report, which was referred to the Reference Committee on Medical Education:

The Board of Trustees appointed a committee to confer with the Board of Regents of the American College of Surgeons and with representatives of the American Hospital Association and the American College of Physicians, with a view to arriving at a satisfactory solution to this problem. At the last meeting of the joint committee, it was suggested to establish a joint commission on hospital standardization to be composed of 18 members representing the four organizations. A rough draft of a proposed constitution and by-laws has been prepared and a copy of it has just been given to the Board of Trustees for study. Negotiations are still going on and much progress has been made. Every effort is being made to reach satisfactory arrangements.

Report of Reference Committee on Medical Education

The reference committee presented the following report, which was adopted:

Your reference committee has given very careful consideration to the statement of the President in his Presidential Address, and to the Supplementary Report of the Board of Trustees in reference to the problem of hospital standardization. Hearings on this report were attended by a large number of members and Fellows, officers and trustees of the American Medical Association, and members of other organizations including executive secretaries and legal representatives.

Your committee appreciates and commends the Board of Trustees on the great amount of effort which has been given to the solution of this problem in the last several months. In June 1950 the Board of Trustees was suddenly faced with a very acute and serious problem which had many implications in regard to the standardization of hospitals. When this problem was presented to the Board of Trustees it seemed almost insurmountable but due to their immediate action and energy great progress has been made toward a satisfactory solution.

After serious consideration of the report and all of the discussion, your committee recommends approval of the action of the Board of Trustees up to this time and also recommends that the study be continued until a satisfactory plan for the standardization of hospitals has been devised.

Supplementary Report of Board of Trustees on Dues

The following report was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

The Board considered the question of the payment of dues in the American Medical Association by physicians who are regarded as hardship cases; that is, those physicians who, for one reason or another, are charged lower local dues and those physicians who can pay local dues but find it a hardship to pay American Medical Association dues, and decided to make the following recommendations to the House of Delegates:

1. If a physician pays only partial dues in his county and state society due to hardship, he will be exempted from payment of American Medical Association dues but will not receive The Journal; this exemption, however, will not be granted except on written recommendation of the secretary of the county or state society that it would be a hardship on the physician to pay the regular dues.

2. If a physician pays full dues in his county and state society, he must pay full dues in the American Medical Association.

Report of Reference Committee on Reports of Board of Trustees and Secretary

The reference committee presented the following report which was adopted:

Your reference committee approves of this report.

Supplementary Report of Board of Trustees on Committee to Study Public Relations

Dr. Louis H. Bauer, Chairman, Board of Trustees, presented the following report which was referred to the Reference Committee on Reports of Board of Trustees and Secretary:

The Board of Trustees has appointed a committee to undertake a study of the public relations of the Association and to draft recommendations as to the future course to be pursued. This committee consists of Dr. Gunnar Gundersen, chairman, and Dr. Edwin S. Hamilton, to represent the Board; and Dr. B. R. Kirklin to represent the House of Delegates. It is hoped that a preliminary report will be made at the February meeting of the Board and a final report rendered to the House of Delegates in June 1951.

Report of Reference Committee on Reports of Board of Trustees and Secretary

The reference committee presented the following report which was adopted:

Your reference committee approves the action of the Board of Trustees in appointing this committee.

Report of Committee on Blood Banks

The Speaker referred the following report of the Committee on Blood Banks to the Reference Committee on Emergency Medical Service:

Through its Committee on Blood Banks, the American Medical Association has cooperated with the American National Red Cross in a national blood procurement program. The several actions of the House of Delegates and of the Committee on Blood Banks regarding blood bank matters from June 1947 to August 1950 have been summarized in a report by the committee at its most recent meeting. The report was submitted to the Board of Trustees on Sept. 15, 1950, which approved it and authorized its publication. Copies may be obtained from the Bureau of Medical Economic Research at Association headquarters. This report contains the full text of the agreement reached in Boston by the several interested groups, and the complete text of the letters from the Secretary of Defense and from the National Security Resources Board designating the American National Red Cross as the military and civilian agency in blood bank matters and the letters of acceptance from the American National Red Cross.

The House of Delegates has endorsed the idea of a national blood procurement program under the auspices of the American National Red Cross. As problems have arisen, the American National Red Cross has at different times expressed a desire to solve them and has made specific agreements with the American Medical Association. In these agreements the American National Red Cross accepted liaison with the American Medical Association through the Committee on Blood Banks. It has been agreed that, to insure safety to recipients, the responsibility for technical details must rest on properly trained personnel under the control of local or state medical societies, and that local control must be exercised by the county medical society, which should be the initial contact in the contemplation of inauguration of a new blood bank. No publicity or news releases are to be issued except by mutual consent of the local county medical society and the local chapter of the American National Red Cross. Differences of opinion in establishment or operation of a blood bank in either administrative or technical detail are to be arbitrated at state levels by joint committees from the state medical society and the American National Red Cross. It has been generally agreed that the principle of blood replacement by the patient, his family, his friends or his organizations is sound, and interbank exchange of blood on a unit for unit basis should be encouraged.

On July 11 and 12, 1950, at a meeting in Boston of the Committee on Blood and Blood Derivatives of the American National Red Cross, together with its Medical Advisory Committee on the National Blood Program, there were present, by invitation, representatives of the American Medical Association, the American Hospital Association and the American Association of Blood Banks. The following agreement, drawn up at this meeting, sets forth the relation among these four organizations in peacetime and in the event of a national emergency:

> Representatives of the American Medical Association, American National Red Cross, American Association of Blood Banks and the American Hospital Association have been meeting to aid in the development of the best possible blood transfusion service for physicians, hospitals and patients who use the blood—in fact, in the interest of national unity throughout the country. After carefully considering the information available, these representatives declared that it seemed advisable to cooperate with the National Security Resources Board by, in time of peace, providing for free exchange of blood between the American National Red Cross Regional Blood Centers and blood banks operating under other auspices on a unit for unit basis whenever and wherever it is needed to serve to the best advantage the interest of the community. It seems advisable for such units to be the property of the recipient blood bank to be used in accordance with its usual policy of issuing blood. As a principle, the groups favor making surplus blood available to the American National Red Cross or other agencies processing blood for the purpose of converting it into derivatives for the benefit of the people. By "surplus blood" is meant all blood that is not required for use as whole blood, plasma or any other derivative by the blood bank concerned.
>
> In the event of a disaster or a national emergency, the American National Red Cross, the American Medical Association, the American Hospital Association and the American Association of Blood Banks favor in those communities not served by an American National Red Cross Regional Blood Center the establishment of such a center and/or the use of existing blood bank facilities to procure the necessary amount of blood. The method to be used should be determined in a manner which meets the approval of the county medical society and the local blood banks and hospitals. Furthermore, the operation of the local blood bank facilities for civilian need should not be interfered with by the emergency program so far as consistent with government regulations existing at that time.
>
> There is definitely a need for the use of standardized equipment and methods for the procurement and dispensing of blood; this is imperative in a national emergency and desirable in time of peace. To insure minimum standards all blood banks cooperating in such a procurement program should meet the minimum standards of the National Institutes of Health.

The Committee on Blood Banks heartily approves the agreement reached in Boston and has been notified of approval by the Board of Trustees. The committee recognizes that the *modus operandi* of this agreement will necessitate many adjustments to meet local conditions. From time to time the committee will report to the Board of Trustees plans for implementation of this agreement with the recommendation that they be published. At an early date the American National Red Cross will request the cooperation of a number of cities in the procurement of blood. When a community is thus selected, the professional groups interested will be invited to work out a program of procurement most suitable for that particular community. This group will include the local Red Cross chapter, the county medical society, local hospitals, local blood banks, if any, and probably the local public health officer.

The American National Red Cross has been designated by the Secretary of Defense as the official procurement agency for blood and blood derivatives for the needs of the armed forces, and the National Security Resources Board has similarly designated the American National Red Cross "to accept the responsibility of coordinating a nationwide civil defense blood program for recruitment of donors and collecting, storing, processing, and preparing for shipment of blood and blood derivatives."

All federal agencies designating the American National Red Cross in blood procurement will charge this organization with the responsibility not only of blood procurement but also of securing necessary correlation and cooperation of other agencies interested in blood procurement. The Department of Defense expects to reimburse the American National Red Cross for actual costs incurred in procurement of blood and blood derivatives for the armed forces.

In its study of the blood bank resources of the United States and possessions, the Bureau of Medical Economic Research of the American Medical Association has found that the 34 regional centers of the American National Red Cross issue less than 15 per cent of the blood used as whole blood. The rest is issued by hospital and nonhospital blood banks. Hence the American National Red Cross must rely on the cooperation of the other blood banks which are currently procuring most of the blood. The American National Red Cross believes it can double its output with present centers and equipment.

The Committee on Blood Banks is of the opinion that a large scale emergency blood program, whether regional or national, can be successful only if the American National Red Cross has the willing and wholehearted cooperation of all other agencies in the blood procurement field. It believes that other blood banks can procure emergency blood under the special motivation that would exist and channel it through the American National Red Cross to the official agencies for which it procures. Joint efforts at the regional, state and local levels are indispensable.

The Committee and the American National Red Cross at their meeting on Aug. 13, 1950 agreed to ratify and confirm all previous agreements, including the "Boston Agreement"; that the American National Red Cross encourage its local chapters, on request of a blood bank cooperating in the emergency program, assist in the procurement of donors for the cooperating blood banks; that in event of local disaster, blood requisitioned from local blood banks by the American National Red Cross be entered as a credit to that bank as in interbank exchange, and that the American Medical Association offer its wholehearted cooperation in the National Emergency Blood Program and encourage other interested organizations to offer theirs.

To assure that this cooperative plan of blood procurement be fully effective, the American Medical Association has recommended to the American National Red Cross that the regional, state and local coordinating organizations of the American National Red Cross Blood Program include full and adequate representation of physicians, hospitals, non-Red Cross blood banks and health departments, state and local. It was also recommended that all public relations, publicity and campaign efforts emphasize the cooperative nature of the National Blood Program, listing the names of the cooperating organizations, and in local areas adding the names of the cooperating blood banks and hospitals. The American Medical Association has further recommended to Mr. W. Stuart Symington, Chairman, National Security Resources Board, that the National Security Resources Board's Advisory Committee on National Emergency Blood Program be continued. The American Medical Association has also recommended to the Department of Defense, the National Security Resources Board and the American National Red Cross that, in deriving formulas for cost reimbursement, consideration be given to the necessity of having such formulas applicable to other agencies cooperating in the emergency blood procurement program.

The Board of Trustees has approved the study of the annual costs of accreditation of blood banks and the problem of integrating such a program with the present hospital inspection program of the Council on Medical Education and Hospitals before steps are taken to carry out the action of the House of Delegates on this matter. This study will be made jointly by representatives from the Committee on Blood Banks, the Council on Medical Education and Hospitals and the Bureau of Medical Economic Research.

After consultation with various advisors, the Committee on Blood Banks concluded that mass typing of the general population is costly and inadvisable for technical reasons, including that of hazards to the patient introduced by dependence on such typing. Previous experiences in mass typing have been disturbing rather than reassuring. On the advice of federal officials, the committee stressed the importance of increasing the production of blood substitutes as well as whole blood in the present emergency.

Criticism of the policy expressed in the above paragraph was submitted by Dr. A. C. Ivy, First Vice Chief Deputy, Emergency Medical and Public Health Services, Chicago Civil Defense Organization, in a letter to the Editor of The Journal. Dr. Ivy's letter was referred to Dr. Leonard W. Larson, Chairman of the Committee on Blood Banks of the American Medical Association. Dr. Ivy's letter and Dr. Larson's comment were published in The Journal, October 28, 1950, page 780.

Supplementary Report of the Committee on Bood Banks

Dr. Leonard W. Larson, Chairman, presented the following report, which was referred to the Reference Committee on Emergency Medical Service:

This report is a supplement to the Report of the Committee on Blood Banks.

Events which have transpired since the meeting of the House last June have greatly complicated the committee's efforts to correlate and coordinate blood banking in the United States for the threefold purpose of furnishing an adequate supply of blood for regular civilian needs, for the military establishment and for civilian emergency needs. So far as the procurement of blood is concerned, we are faced at this time with the emergency we have long been planning to meet. The responsibilities placed on the American National Red Cross both by the Department of Defense and by the National Securities Resources Board as indicated in the printed portion of our report have been greatly augmented by the events of the past few weeks and demand the full cooperation of every American agency in any way related to blood procurement. In this cooperation the American Medical Association has a leading part.

The committee would desire to emphasize that at this time the national emergency blood program is and must continue to be a three-pronged activity, each part of which must be developed to keep the whole program in balance. These three parts are (1) the maintenance of supplies of blood and plasma for normal civilian requirements, (2) the furnishing of whole blood and plasma to the Armed Forces of the United States and (3) the development of dispersed reserve supplies of equipment for collecting blood and dispersed reserve supplies of blood plasma for civilian defense.

The Red Cross has been exerting continuous pressure on all of its regional blood centers by increasing their quotas of blood procurement for military emergency needs. While these regional centers will very shortly be procuring much more blood than the stepped up quotas they are now meeting, the American National Red Cross relies on the participation of all other blood procuring agencies in the national emergency blood program.

At a meeting of all participating organizations held in Washington in September, it was agreed that the American National Red Cross should set up in various cities in the United States special defense blood collection centers, and that in the cities so designated local committees of all participating organizations would determine what in the opinion of the local committee was the best method of collecting blood in its city. The committee reemphasizes its previous recommendation that full credit be given in publicity at the local level to all participating organizations and that this recommendation be called to the attention of the new president of the American National Red Cross.

Under the national emergency blood program contractual relationships have been established with all companies equipped to process blood into dried plasma and serum albumen. The capacity of these plants is being expanded and during 1951 the blood requirement will likely strain the facilities and personnel of all existing blood banks in the United States. The first shipment of whole blood to Korea was made on Aug. 25, 1950, and many shipments of type "O" blood have been made since. These have been made possible both through the increased quotas of Red Cross regional blood centers and also through the active participation of many other blood banks, particularly of those located on the West Coast.

The pattern of cooperation in the blood program will vary according to local conditions in the several states. The committee recommends in order to avoid duplication and overlapping of effort and the confusion resulting therefrom, that each state medical society see to it that a state committee on blood banks be established whose function it would be to correlate the elements of the emergency blood program in its state and to see that the blood procured is properly channeled. These committees should include representation from hospitals, blood banks and the Red Cross.

The committee has had the benefit of valuable and helpful information furnished by Drs. Albert E. Heustis, George D. Cummings and J. H. Ahronheim, Col. A. D. Howell of the State of Michigan and Dr. Lamar Soutter of Massachusetts regarding their current and planned programs for public participation in the emergency blood program.

The committee is of the opinion that the most important problem in the blood program facing the American people is the procurement of large amounts of blood and plasma for military and civilian defense purposes and the dispersal of plasma and of blood equipment intended for civilian defense uses to strategic points in the United States and possessions. The American Medical Association at this time urges the President and the Congress of the United States to make available at the earliest possible moment the necessary funds to expedite this program. The Association also urges on all community leaders in the United States that no steps be taken at this time which will divert public attention from the main problem. It is most likely that a complete and fool-proof civil defense program for the United States which would cover all risks could conceivably bankrupt the country; therefore, it is necessary in this field, as in all others, that concentration must be focused on the principal objectives with certain calculated risks.

A system of voluntary accreditation of blood banks should remain among the aims of the American Medical Association. In view of current conditions, however, the committee recommends deferring the question for the present. Meanwhile, blood banks participating in the national emergency blood program should meet, as a minimum, the standards of the National Institutes of Health.

The committee is continuing its statistical study of blood banks to obtain data on capacity and utilization. The special blood bank questionnaire sent in July to all blood banks listed in Bulletin 75 of the Bureau of Medical Economic Research has revealed that, in the event of a grave disaster, the number of donors who can be bled simultaneously can be increased threefold by hospital blood banks and twofold by nonhospital blood banks and Red Cross regional blood centers. (This refers to *present* equipment and personnel and to *simultaneous* bleeding capacity—not to the total amount of blood which could be drawn in one week or one month.) The amount of blood used annually by all hospitals can be estimated again only after analysis of the replies to the questions on blood included in the current hospital questionnaire for 1950 sent by the Council on Medical Education and Hospitals to all registered hospitals. The two analyses will be combined into a single study which should be completed before the next meeting of the House of Delegates.

REPORT OF REFERENCE COMMITTEE ON EMERGENCY MEDICAL SERVICE

The Reference Committee on Emergency Medical Service to which these reports were referred reported as follows and the House adopted its report:

The report of the Committee on Blood Banks and its supplementary report is an outstanding contribution to a subject that is deserving of our most important consideration in the present emergency. A perusal of the reports is indicative of the careful thought and study given the matter.

The report covers in detail the agreement at a meeting in Boston July 11 and 12, 1950, of the Committee on Blood and Blood Derivatives of the American National Red Cross, together with its Medical Advisory Committee on the National Blood Program. At this meeting by invitation were representatives of the American Medical Association, the American Hospital Association and the American Association of Blood Banks. The agreement sets forth the relation among these four organizations in peacetime and in the event of a national emergency. The Committee on Blood Banks approved the agreement reached in Boston, and it has also been approved by the Board of Trustees.

The committee is of the opinion that the most important problem in the blood program at this time is the procurement of large amounts of blood and plasma for military and civilian defense purposes and blood equipment intended for civilian defense uses at strategic points in the United States and its possessions. Your committee concurs in this opinion.

In its supplementary report the committee recommends that a state committee on blood banks be established in each state whose function would be to correlate the elements of the emergency blood program in its state. Your committee approves of this recommendation.

In the opinion of your committee, we are faced with a real emergency. The time for talk is past. The time for action is here. Let us be realistic. The Committee on Blood Banks has told you what must be done. They cannot do it, neither can it be done at 535 North Dearborn Street. What we need is more blood and blood derivatives. This can only be done by expanding existing blood centers and establishing new ones in hospitals and laboratories and training the personnel necessary for this increased program. This can best be done, in our opinion, on the state and local levels with the full cooperation of the American Red Cross and every other American agency in any way related to blood procurement. And speaking of cooperation, your committee thinks it is hardly necessary to call your attention to the leading part the American Medical Association has taken in this movement.

It would therefore recommend (1) that the Board of Trustees, through whatever committee it may designate, strongly urge that a state committee on blood banks be promptly established in all its constituent associations, if not already established; (2) that these committees be advised of the necessity of full cooperation with all other agencies engaged in blood procurement programs; (3) that this state committee on blood banks proceed to develop promptly a blood program, having in mind the statement in the supplementary report that it must be a three-pronged activity, each part of which must be balanced to keep the whole program in balance, and (4) that a copy of the report of the Committee on Blood Banks and of its supplementary report be sent to the secretary of each constituent association for the information of its blood bank committee if in existence or to be established. Your committee trusts that all the delegates will carry back to their associations the information and recommendations of the Committee on Blood Banks and convey to their officers the emergency we are facing and the importance and the necessity of their prompt cooperation in the blood procurement program.

Report of Judicial Council

Dr. E. R. Cunniffe, Chairman, Judicial Council, presented the following report, which was referred to the Reference Committee on Medical Education:

This report will deal with activities of the Judicial Council since the American Medical Association Clinical Session held at Washington in December 1949.

Several meetings have since been held, one on May 5, 1950 in Chicago, several in June in San Francisco and a subsequent meeting on September 29 in Chicago.

The questions presented at these meetings consisted frequently of complaints concerning the ethical conduct of individuals suspected of violating the Principles of Medical Ethics which should first have been considered by the county medical society. Such complaints are frequently referred by the Council back to the component society since they are the only organizations in our federated association with penal powers. An original decision by the Judicial Council in answer to some of these communications would prejudge the accused member and he, as an appellant, would then come for his final hearing to a prejudiced court.

Other questions were answered personally by the chairman, expressing merely his own opinion with the assurance that the subject matter would be submitted to the Judicial Council for its decision at the next meeting.

There were also considered the applications of candidates for Fellowship whose eligibility was questioned. Also those names presented for Honorary or Affiliate Fellowship were considered and recommended for election by the House of Delegates.

The following portion of the report of the Committee on Hospitals and the Practice of Medicine was referred to the Council by the Board of Trustees for opinion:

"If and when a physician is found to be unethical by the proper authorities as established through channels specified in the Constitution and By-Laws, and he is still retained on the staff of any hospital approved for resident or intern training by the Council on Medical Education and Hospitals, it shall be the duty of the Judicial Council to request the Council on Medical Education and Hospitals to show cause as to why that Council should not remove such hospital from the approved list under the assumption that the hospital is just as unfit for the training of young physicians for unethical reasons as it is unfit because it may not or does not have proper filing systems for its laboratory or clinical records."

After due consideration the Council approves this portion of the report, and suggests modification of this section, deleting the words ". . . to show cause why that Council should not remove such hospital from the approved list." The modification would read as follows: "It shall be the duty of the Judicial Council to request conference with the Council on Medical Education and Hospitals on the advisability of removing such hospitals from the approved list."

At the last meeting of the House of Delegates, the following supplementary report of the Committee on Hospitals and the Practice of Medicine was referred to the Judicial Council:

"The Committee believes that if the following pattern were followed the possibility of solving any controversy between physician and hospital would be greatly improved:

"When a physician believes he has a legitimate complaint against hospital management, he should first attempt to solve the difficulty at the staff level. And it is incumbent on the medical staff to assist in arriving at a fair and proper solution.

"If no solution is reached at this level, the physician should appeal to the appropriate committee of his county medical society for advice and assistance. The county medical society committee should develop methods for contacting hospitals, management and boards, as well as local associations representing hospitals, in order that all sides of the controversy may be understood and personality difficulties minimized.

"When a solution seems impossible through the good offices of the county medical society, mechanisms should be available for presentation of the matter to the state medical association of which the physician is a member. Here, again, for the purpose of receiving all available facts and opinions, the state medical association should develop liaison with the state hospital association.

"To facilitate the consideration and mediation of physician-hospital controversies, specific authorization to handle such matters should be given to some committee of both county and state medical societies. In the larger county societies and the state associations this function could be best carried out through a special committee created for just this purpose. It should be the function of such committees to mediate differences in the light of the existing state laws, the Principles of Medical Ethics and the best interests of the patients.

"The services of the Correlating Committee on Extension of Hospitals and Other Facilities of the Council on Medical Service, working with a similar committee of the American Hospital Association, should be available to study and assist in solving physician-hospital problems which seem unsolvable at the local and state levels. For formal opinion or adjudication, however, the portfolio should be presented to the Judicial Council."

The Judicial Council approves of this report and feels its recommendations should be accepted by all state associations and component societies and steps taken to expedite the carrying out of the provisions of this program. The Council note with satisfaction that several such committees have already been appointed by several state associations and component societies.

Members of the Judicial Council particularly enjoy the not infrequent requests that are received from other professional groups for advice or for copies of the Principles of Medical Ethics as a guide to the development of similar guidance in professional conduct.

Students taking ethics for the subject of a thesis ask for copies of the booklet of Principles and seek our advice on related subjects. The Principles of Medical Ethics are acknowledged to be the highest of any profession except that of the clergy, whose principles are derived from the tenets of their individual religion. All these should lead to united effort to maintain our exalted ethical standards.

Respectfully submitted,

Edward R. Cunniffe, Chairman.
Walter F. Donaldson.
H. L. Pearson Jr.
J. B. Lukins.
Louis A. Buie.
George F. Lull, ex officio.

Report of Reference Committee on Medical Education

The reference committee presented the following report, which was adopted:

After due consideration your reference committee recommends that the report of the Judicial Council be approved and further recommends that the House of Delegates concur in its recommendations.

Supplementary Report of Board of Trustees on Federal Aid to Medical Education

Dr. Louis H. Bauer, Chairman, Board of Trustees, presented the following report, which was referred to the Reference Committee on Medical Education:

The American Medical Association has been asked whether it would modify its stand on federal aid to medical education for the period of the emergency.

The following points should be borne in mind:

1. All medical schools are at present operating at or nearly at capacity. Enrolment in medical schools is at an all time high.

2. Any further increase in enrolment can be accomplished only in one of two ways: (*a*) by increasing physical facilities and teaching personnel or, (*b*) by decreasing standards in medical education.

3. Even if increased enrolment were now possible, it would be four years before any additional doctors could graduate. To increase enrolment by increasing physical facilities will require considerably longer than the four years above mentioned.

4. Therefore, it is doubtful if the emergency can be helped no matter what procedure is adopted and the problem should be considered rather from its long range aspect.

The attitude of the American Medical Association on federal aid to medical education has been misconstrued and often deliberately so.

The American Medical Association would not oppose federal aid to medical education if it could be assured of two things: First, that any legislation would guarantee absolute freedom of medical education from government control; second, that all sources of private support for medical education have been exhausted. Up to the present, neither of these is assured.

The American Medical Association recognizes that some medical schools are now in financial difficulties, and in view of the national emergency may face greater ones. The extent of these financial difficulties has not been made clear. Recognizing the greater or less need for financial assistance to medical schools beyond what they are now receiving, the American Medical Association nevertheless believes that further efforts should be made to obtain these funds from private sources. Furthermore, the Association is willing to lend its support to a campaign for raising funds for medical education among the professions, industry and labor. It urges that such an all out drive be started immediately.

In formulating any plan for emergency medical service, consideration should be given to several factors: 1. Economical use of medical man power by establishing and maintaining a proper balance between military and civilian needs; 2. Provision for rotation of doctors in the armed services so as to equalize the burden on the individual and disrupt as little as possible the teaching faculties and thus allow for a continuous progression of trained specialists and practitioners into the active professions; 3. The flow of properly trained students into the medical schools should be continued at the present or a greater level; 4. Postgraduate instruction should be maintained or increased so as to provide the number of doctors required not only in specialties but in general practice.

REPORT OF REFERENCE COMMITTEE ON MEDICAL EDUCATION

The reference committee presented the following report which was adopted:

Your reference committee recommends approval of this report.

Report of Interim Committee on Constitution and By-Laws

Dr. Joseph D. McCarthy, Chairman, presented the following report:

Mr. Speaker and Members of the House of Delegates:

RESOLUTION ON AMENDMENTS TO CONSTITUTION AND BY-LAWS FOR ADDITION OF COMMITTEE ON CONSTITUTION AND BY-LAWS TO STANDING COMMITTEES

WHEREAS, The Interim Committee on Constitution and By-Laws believes that it is important that the American Medical Association have a permanent Committee on Constitution and By-Laws so that the Constitution and By-Laws of the American Medical Association may be kept up to date and that suggestions and resolutions which would amend the Constitution and By-Laws may be given careful study; and

WHEREAS, The Interim Committee on Constitution and By-Laws is unanimously of the opinion that a special committee should be provided which would act during the interim between meetings of the House of Delegates of the American Medical Association as a fact finding and advisory committee relative to matters pertaining to the Constitution and By-Laws so that the House of Delegates would have the benefit of its research; therefore be it

Resolved, That Chapter X of the By-Laws, Section 4(B) be amended to include a new final paragraph which will read as follows:

> The standing Committee on Constitution and By-Laws shall consist of five Member or Service Fellows elected by the House of Delegates on nomination of the Board of Trustees for terms of five years, so arranged that at each annual session the term of one member expires. At the 1951 annual session one member shall be elected for a term of one year, one for two years, one for three years, one for four years and one for five years. The President, Secretary, Assistant Secretary, a member of the Board of Trustees and the Speaker and Vice Speaker of the House of Delegates shall be ex officio members of this committee without the right to vote.

and to include a new paragraph (5) under (I) DUTIES, as follows:

> This committee shall be a fact finding and advisory committee on matters pertaining to the Constitution and By-Laws. It shall report to the House of Delegates.

SINGLE MEMBERSHIP CLASSIFICATION

The Interim Committee on Constitution and By-Laws was instructed by the House of Delegates during the 1950 Annual Session to study the merits of proposals made by some to amend the Constitution and By-Laws whereby it would provide for one general classification of members. This single membership classification would entitle all members to all rights and privileges now accorded to members and Fellows.

Your committee has deliberated this question at length, each member stating his reasons in writing for his ultimate conclusions.

The opinions expressed by the individual members unanimously oppose any amendment to the Constitution and By-Laws which would change the present distinction between a member and a Fellow.

The Interim Committee on Constitution and By-Laws recommends to the House of Delegates that the membership and Fellowship classification provided for in the 1950 edition of the Constitution and By-Laws be retained.

PROPOSED AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

The following proposed amendments to the Constitution and By-Laws have been given serious consideration by your committee, which unanimously recommends their adoption.

The amendments to the Constitution will lay over until the next meeting of the House of Delegates. The amendments to the By-Laws, following the recommendations of the Reference Committee on Amendments to the Constitution and By-Laws, can be adopted at this session.

CONSTITUTION

1. Amend Article 5, Section 1 (B) to read: "Associate Members.—Associate membership in the American Medical Association shall be limited to those members of constituent associations who are not active members of the American Medical Association or the constituent association and who hold the degree of Doctor of Medicine or Bachelor of Medicine, subject to the provisions of the By-Laws."

Amend Article 5, Section 1 by adding new paragraph: "(C) A member shall retain his active or associate membership as long as he complies with the provisions of the Constitution and By-Laws and with the Principles of Medical Ethics of the American Medical Association."

2. Amend the last sentence of Article 6, Section 2 so that it will read: "The general officers, the past Presidents of the Association, the General Manager, the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the chairmen of the several standing committees and two delegates elected by the Student American Medical Association shall be ex officio members of the House of Delegates without the right to vote."

3. Amend the first sentence of Article 6, Section 3, so that it will read: "The number of delegates from the constituent associations shall be proportional to the number of dues paying active members of the American Medical Association in the respective constituent associations as provided in the By-Laws."

4. Amend Article 11 so that the first sentence will read: "Funds may be raised by equal annual dues or by assessment on each of the active members on recommendation by the Board of Trustees and after approval by the House of Delegates."

BY-LAWS

5. Amend Division One, Chapter II, Section 2, the first sentence, so that it will read: "Sec. 2. Dues.—Annual dues may be prescribed for the ensuing calendar year in an amount recommended by the Board of Trustees and approved by the House of Delegates."

and amend the same paragraph by inserting the following new third sentence, "The Board of Trustees may excuse a member from paying dues when it is deemed advisable, provided that he is excused from the payment of full dues by his component society and constituent association."

and further amend the last sentence of the same paragraph by deleting the words, "such subscription to begin Jan. 1, 1951," so that the sentence will read: "Dues shall include subscription to THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION."

Amend the same Section 2 of Chapter II, so that it shall read: "An active member is delinquent if his dues are not paid by December 31 of the year for which dues are prescribed and shall forfeit his active membership in the American Medical Association if he fails to pay the delinquent dues within 30 days after the notice of his delinquency has been mailed by the Secretary of the American Medical Association to his last known address."

6. Amend Division Two, Chapter IV, Section 2, the fifth paragraph, so that the first two sentences will read: "A Member Fellow shall pay annual Fellowship dues which shall be determined by the Board of Trustees and announced in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. It shall be the privilege of a Member Fellow to subscribe for any other scientific journal published by the Association in lieu of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION to which he is entitled as a member."

and further amend Division Two, Chapter IV, Section 2, so that the last sentence of the fifth paragraph becomes a new paragraph.

7. Amend Division Two, Chapter IV, Section 2 (C), last sentence to read: "Affiliate Fellows shall pay Fellowship dues and shall enjoy the privileges of the Scientific Assembly without the right to vote or hold office."

8. Amend Division Two, Chapter V, so that the second category shall read: "(2) Active or Associate Members;"

9. Amend Division Two, Chapter VII, Section 3, first sentence to read: "The officers of each section shall be a chairman, a vice chairman, a secretary, the delegate, a representative to the Scientific Exhibit and such other officers as the section . . . ."

10. Amend Division Two, Chapter VII, Section 5, by adding the following new paragraph:

"(D) Section Representatives to the Scientific Exhibit.—The section representatives shall assist the Committee on Scientific Exhibit of the Board of Trustees in obtaining outstanding scientific exhibits and advise the Committee on the selection of material submitted and on all other matters pertaining to exhibits in their respective specialties."

11. Amend Division Three, Chapter IX, Section 1, (A) so that this paragraph shall read: "In order to be eligible for election to membership in the House of Delegates, a physician must have been a dues paying active member of the American Medical Association and a Member Fellow of the Scientific Assembly for at least the two years immediately preceding the session of the House at which he is to serve. Service Fellows need not be dues paying active members."

12. Amend Division Three, Chapter IX, Section 1 (B), second paragraph to read: "Secretaries of constituent associations, secretaries of sections of the Scientific Assembly, the Surgeons General of the United States Army, the United States Navy, the United States Air Force and the United States Public Health Service and the Chief Medical Director of the Veterans Administration shall certify delegates and alternates to the Secretary of the American Medical Association."

13. Amend Division Three, Chapter IX, Section 1 (C) to read: "The opportionment of delegates from each constituent association shall be one delegate for each thousand (1,000) or fraction thereof, dues paying active members of the American Medical Association as recorded in the office of the Secretary of the American Medical Association on December 1 of each year."

14. Amend Division Three, Chapter X, Section 4 as follows: "Sec. 4. Standing Committees.—(A) The following are the standing committees of the House:"

and add as a final category,

"(5) Committee on Constitution and By-Laws."

and further amend Chapter X, Section 4 by adding the words "and Committees" after the words "The Councils" in the first sentence of paragrph (C), and by adding the words, "and Committee" after the words, "Each Council" in the first sentence of paragraphs (D) and (E);

and amend the same section, Paragraph (F) to read: "(F) Each Council and Committee shall have authority to appoint subcommittees subject to the approval of the Board of Trustees for any purpose within the functions of the Council or Committee."

and further amend the same section by adding the words, "and Committees" at the end of Paragraph (G) so that that paragraph will read: "(G) Headquarters—The Association headquarters shall be the headquarters of all Councils and Committees."

and further amend the same Section by adding the words, "and Committee" after the words "Each Council" in the first sentence of paragraph (H).

15. Amend Division Three, Chapter X, Section 5, (D) (4) to read: "(4) Medical Education and Hospitals, to which shall be referred all matters relating to medical education and hospitals."

16. Amend Division Three, Chapter XII, Section 6, by adding final paragraph "(I) Be an ex officio member of all standing committees of the House of Delegates and the Board of Trustees without the right to vote."

17. Amend Division Three, Chapter XIII, Section 4, (C) to read as follows: "(C) Appoint an editor or editors for all or any of the Association's publications. The Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION shall be an ex officio member of all standing committees of the House of Delegates and the Board of Trustees without the right to vote."

and further amend the same section by adding a new paragraph "(E) Appoint an Assistant Secretary. He shall be an ex officio member of all standing committees of the House of Delegates and the Board of Trustees without the right to vote."

This amendment necessitates the relettering of the remaining paragraphs of Section 4, so that former paragraphs (E), (F) and (G) will become paragraphs (F), (G) and (H) respectively.

Respectfully submitted,

JOSEPH D. MCCARTHY, Chairman.
LOUIS A. BUIE.
EDWIN S. HAMILTON.
STANLEY H. OSBORN.
BRITTON E. PICKETT.
FLOYD S. WINSLOW.
and ex officio
FRANK F. BORZELL.
ERNEST B. HOWARD.
GEORGE F. LULL.
JAMES R. REULING.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO CONSTITUTION AND BY-LAWS

This report was referred to the Reference Committee on Amendments to the Constitution and By-Laws, which presented the following report which was adopted and the By-Laws amended as indicated while the proposed amendments to the Constitution will lie over until the annual session in June, 1951:

1. Your committee approves the resolution of the Interim Committee on Constitution and By-Laws and recommends its adoption.

2. The proposed amendments offered by the Interim Committee on Constitution and By-Laws are recommended for adoption with the following amendment: That in the sentence reading "The general officers, the past Presidents of the Association, the General Manager, the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the chairmen of the several Councils" etc., the word "Councils" shall be changed to "standing committees."

Supplementary Report of Board of Trustees on Resolution on Council on Federal Medical Services

Dr. Louis H. Bauer, Chairman, Board of Trustees, presented the following report, which was referred to the Reference Committee on Insurance and Medical Service:

During the June 1950 Session of the House of Delegates Dr. James C. Sargent introduced a resolution entitled, "Resolution on Council on Federal Medical Services." On recommendation of the reference committee, the resolution was referred to the Board of Trustees for further study. After further study the Board of Trustees referred the Resolution to the Council on Medical Service with the suggestion that the Council's Committee on Medical Care of Veterans "be expanded to include federal personnel."

The Council is in agreement with the suggestion of the Board of Trustees and recommends to the House of Delegates that the name of the Council's Committee on Medical Care of Veterans be changed to Committee on Federal Medical Services. On approval of this recommendation, the Council will enlarge the personnel of this Committee to meet the requirements of the specific functions enumerated in the resolution; that is, (*a*) advising the Board of Trustees on all aspects of the several forms of federally supplied medical care either now or to be established; (*b*) serving the Board of Trustees and the Association in conference with and in representations to both nongovernmental and governmental agencies interested in the several forms of federally supplied medical care; and (*c*) advising the House of Delegates at each of its regular and special sessions on any policy or change in policy of the Association relating to the several forms of federally supplied medical care which may require its consideration and action.

In order to carry out these functions, the Council recognizes the necessity of the fullest possible cooperation between this Committee, the Council on National Emergency Medical Service, the Committee on Chronic Diseases, the Washington Office and *other councils, bureaus, and committees within* the Association.

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

The reference committee presented the following report which was adopted:

In the Supplementary Report of the Council, the section on Federal Medical Services, the committee recommends the approval of lodging this function in the present Council Committee on Medical Care of Veterans and the change of the name to the Committee on Federal Medical Services; it recommends that the three paragraphs on the functions of the Committee, *a*, *b*, and *c*, be corrected accordingly so that in *a* the words "Council on Medical Service" will be substituted for the words "Board of Trustees," in *b*, the words "Council on Medical Service" will be substituted for the words "Board of Trustees and the Association," and in *c*, the words "Council on Medical Service" be substituted for the words "House of Delegates." These corrections are made in line with the mechanical changes suggested.

Report of Council on Medical Education and Hospitals

The Report of the Council on Medical Education and Hospitals (See THE JOURNAL, Oct. 21, 1950, pages 662-666) was referred to the Reference Committee on Medical Education, which reported as follows and the report was adopted:

Your reference committee has considered the report of the Council on Medical Education and Hospitals. Your committee commends the Council for the splendid service which it has rendered and for the clear and concise report which it has made of its many activities in the past year. It is recommended that all members of the House of Delegates read the report of the Council on Medical Education and Hospitals. Your committee expresses the hope that the Council on Medical Education and Hospitals will continue its consideration of the critical problem of medical education in the current emergency as well as the Survey of Medical Education. Your committee has considered the report of the Council on the financial support of medical schools.

Your committee recommends the approval of the report of the Council on Medical Education and Hospitals.

Report and Supplementary Report of Council on Scientific Assembly

The Speaker referred the Report of the Council on Scientific Assembly (See THE JOURNAL, Oct. 21, 1950, page 667) and its following supplementary report to the Reference Committee on Sections and Section Work:

To the Members of the House of Delegates of the American Medical Association:

The Council met on November 17 in Chicago and on December 4 in Cleveland. The Conference of Section Secretaries also met with the Council in Chicago on November 17.

SECTION ON ALLERGY

On November 17 a request to recommend the establishment of a Section on Allergy was presented to the Council by Dr. Harry L. Huber of Chicago. After due consideration, the Council voted to recommend to the House of Delegates that a Section on Allergy be not established at this time. At the same meeting, the Council voted to grant a Session on Allergy in the Section on Miscellaneous Topics at the 1951 Atlantic City Annual Session.

1951 ATLANTIC CITY ANNUAL SESSION

No change in the general form of the Scientific Assembly is anticipated for the 1951 Annual Session The section secretaries have their programs well advanced and the Council has already filled most of the places on the list of speakers for the General Scientific meetings.

1951 HOUSTON CLINICAL SESSION

The Council notes with pleasure the appointment by the Board of Trustees of Dr. James T. Billups, of Houston, Texas, as Chairman of the Local Committee on Arrangements for the Houston Clinical Session, to be held Dec. 4-7, 1951. Conferences with Dr. Billups have already been held and the Council plans to meet in Houston in March of next year.

The Southern Medical Association meets in Dallas a few weeks prior to the Clinical Session of the American Medical Association in Houston. Both associations may suffer from the close juxtaposition of these two meetings. There is bound to be considerable duplication in audience and in speakers who participate in the clinical lectures or presentations. This also applies to exhibitors, both commercial and scientific.

In view of a contract already signed with the Houston authorities, the Council will do its best to provide a suitable program, depending largely, as usual, on the Local Committee on Arrangements. The addition of Dr. Samuel P. Newman of Denver to the membership of the Council to fill out the unexpired term of Dr. Larson, now a member of the Board of Trustees, should be helpful to the Houston Committee, as he was responsible for the splendid program arranged for the Denver Clinical Session in 1950, which had to be suddenly given up when the meeting was transferred to Cleveland.

1950 CLEVELAND CLINICAL SESSION

The Council desires to express its appreciation at this time to the Local Committee on Arrangements for the 1950 Cleveland Clinical Session. Headed by an able chairman, Dr. Fay A. LeFevre, all members of the committee are to be congratulated on the exhibits, the television and clinical programs of high quality presented at this Clinical Session.

REPORT OF REFERENCE COMMITTEE ON SECTIONS AND SECTION WORK

The reference committee presented the following report, which was adopted:

Your Reference Committee on Sections and Section Work wishes to make the following report:

1. Your reference committee had referred to it the report of the Council on Scientific Assembly together with a supplementary report, in which the Council had made certain specific recommendations:

A. Section on Military Medicine: After duly considering the request made by the House of Delegates at the last Annual Session in San Francisco that a Section on Military Medicine be established, the Council on Scientific Assembly has recommended the establishment of a new Section on Military Medicine. Your reference committee has given this matter serious thought and is in full accord with this action of the Council, particularly now that the importance of military medicine in the national defense in our present emergency has taken on added significance. Your reference committee therefore recommends to the House of Delegates the establishment of a new Section on Military Medicine.

B. Change in name of Section on Preventive and Industrial Medicine and Public Health: Your reference committee is in agreement with the recommendation of the Council that the name of the Section on Preventive and Industrial Medicine and Public Health not be changed.

C. Section on Medicine in Industry: Your reference committee approves the recommendation of the Council that a Section on Medicine in Industry not be established.

2. Resolution on Change in Name of Section on Nervous and Mental Diseases: Your reference committee, after due consideration, recommends that this resolution be disapproved.

3. Your reference committee has reviewed the work of the Council on Scientific Assembly and wishes to express appreciation for its splendid accomplishments.

Report and Supplementary Report of Council on Medical Service

The Speaker referred the Report of the Council on Medical Service (See THE JOURNAL, Oct. 21, 1950, pages 668-670) and its mimeographed supplementary report to the Reference Committee on Insurance and Medical Service, which presented the following report which was adopted:

The printed portion of the report of the Council on Medical Service deals chiefly with Committees of the Council, Indigent Medical Care, Grievance Committees, the Physicians Placement Service and the Distribution of Printed Material. The committee feels the Council has planned well and accomplished much within the limits of its budget and staff. The committee recommends the approval of the printed report.

In the supplementary report of the Council, the Section on Federal Medical Services, the Committee recommends the approval of lodging this function in the present Council Committee on Medical Care of Veterans and the change of the name to the Committee on Federal Medical Services, it recommends that the three paragraphs on the functions of the Committee *a*, *b*, and *c*, be corrected accordingly so that in *a* the words "Council on Medical Service" will be substituted for the words "Board of Trustees," in *b*, the words "Council on Medical Service' will be substituted for the words "Board of Trustees and the Association,' and in *c*, the words "Council on Medical Service" be substituted for the words "House of Delegates" These corrections are made in line with the mechanical changes suggested

The recommendations regarding possible policy concerning temporary disability compensation insurance were reviewed and many witnesses with varying viewpoints were heard Some information on the subject was contained in the Council's report and witnesses presented a number of exhibits based on the subject It was ascertained that a complete digest of the information that the Council's staff has assembled has not as yet been made and until this has been done it is doubtful whether the House of Delegates will be in a position to formulate a complete policy respecting the best methods of providing such coverage It appears that the Council will be able to supply this to every member of the House of Delegates early in May and the committee recommends that it do so In the interim, the Council is in a position to supply the information it has to any state societies needing it

It is recommended pending the establishment of a policy on the subject of temporary disability compensation insurance that the following minimum safeguards ought to be observed

1 In the case of possible legislative enactment the prevention of abuse and extension of the program into allied fields,

2 Limitation of benefits to cash indemnity,

3 Limitation of physician's duty to reports on diagnosis, prognosis and ability to work

4 Provision of medical supervision or review for maintenance of suitable standards of reporting

On the subject of Voluntary Health Insurance, the House should note the commendable progress outlined in the report

The House should reiterate at this time the necessity for the expansion of benefits offered under voluntary service plans as rapidly as will be consistent with sound insurance practice Among those attention is drawn not only to catastrophic coverage, and home and office service coverage, but particularly the extension of periods of grace occasioned by temporary unemployment

The conferences on the provision of nursing services are most praiseworthy and approval of that portion of the report is recommended with the deletion of the paragraph which follows the listing of eight problems to be considered, the paragraph which makes reference to commercial carriers

The recommendations with respect to relations with lay sponsored voluntary health plans outlining the mechanism and mode of accreditation are well thought out and the committee recommends their approval

The committee desires to make the following general observations regarding the functions of the Council on Medical Service with recommendations to the House

The Council on Medical Service has within its sphere of activity some of the principal responsibilities of the American Medical Association relating to the positive program of the Association in making studies and devising means for getting more and better medical care to the American people With particular approval the committee has heard the statement from the Chairman of the Board that the support of the Council's activities is to be increased Hitherto the Council has conducted its activities with a very small staff and very limited appropriations The committee believes that the staff has been insufficient even to make an expert analysis of the data the Council possesses The committee envisages in the immediate future the necessity for proceeding on a greatly expanded program of studies and the active promotion by the American Medical Association in all needful areas of every sound means of supplying medical service Among many needed projects might be mentioned pilot studies in the provision of care, in the further discovery of local gaps in medical care, and the establishment of a revolving fund to be utilized in the physician placement service Furthermore, war conditions are likely to produce dislocations of medical service which will furnish special and urgent problems for the Council A greatly augmented staff strengthened in every particular, is requisite The members of the Association have demonstrated that they can mobilize funds for the negative aspects of our program and it is now shown that they are just as willing to accumulate large amounts for the positive phase The House might well indicate to the Board its entire support for the greater extension of the functions of this Council for the purpose mentioned and the committee so recommends

Resolution on Facilities of the American Medical Association Available in Serving the Nation

Dr R B Robins Arkansas, presented the following resolution which was adopted:

Whereas, Our nation and the United Nations are now facing the most fateful decisions in their history in protecting and preserving the liberties and freedoms for which they were created, and

Whereas, The undeclared war now being waged against the United States and the United Nations in Korea is growing more serious hourly, and

Whereas, Our nation and the other free nations of the world require at this hour and in the ominous days and weeks ahead the fullest support of our united peoples, and

Whereas, This situation imposes on the medical profession both in the care of our fighting men and of our civilian populations the heaviest of responsibilities, and

Whereas, The American Medical Association, acting through its House of Delegates and representing its 148 000 members desires to discharge fully these responsibilities in serving the men of the armed forces and the civilian population, therefore be it

Resolved, By the House of Delegates of the American Medical Association that the President of the United States, as Commander in Chief of our armed forces be informed that the facilities of the American Medical Association will be used in all ways possible and necessary in serving the nation and in providing the best of medical care to soldier and civilian alike

Resolution on Absentee Ballot

Dr James Z Appel, Pennsylvania, presented the following resolution

Whereas, It is the duty of every citizen of the United States to exercise his or her privilege of the ballot, and

Whereas, There is a great variation in the laws of the states regarding absentee ballots some states having no absentee ballots, others having such ballots but regulations being such that make it extremely difficult to exercise a vote by absentee ballot, and

Whereas, During election week of 1950 several state regional and national medical organizations held sessions thus preventing their membership from exercising their privilege of the ballot, therefore be it

Resolved, That the House of Delegates of the American Medical Association request the Board of Trustees to memorialize all medical organizations regarding the error of scheduling state, national and regional medical meetings at times of election

REPORT OF REFERENCE COMMITTEE ON MISCELLANEOUS BUSINESS

The Reference Committee on Miscellaneous Business, to which this resolution was referred, submitted the following report, which was adopted

Your Reference Committee on Miscellaneous Business heartily agrees with the intent of the resolution and feels that it is inconsistent and unthoughtful for medical organizations to urge doctors to get out and vote and then arrange meetings which interfere with this privilege Your committee requests that editorial comment be made on this problem in THE JOURNAL of the American Medical Association in order that the purpose of this resolution may be implemented It, therefore, recommends the adoption of this resolution

Resolutions on Hospital Standardization Program

Dr James Z Appel, Pennsylvania, presented the following resolutions

Whereas, The House of Delegates of the American Hospital Association at its recent meeting at Atlantic City authorized the trustees of the American Hospital Association to establish a Hospital Standardization Program, and

Whereas, The American College of Surgeons did express a desire to withdraw from the hospital standardization field, now, therefore, be it

Resolved, That the House of Delegates of the American Medical Association expresses its disapproval of (1) the plans of the American Hospital Association regarding the existing hospital standardization program of the American College of Surgeons and (2) the plan of the American Hospital Association to establish a hospital standardization program either as an independent enterprise or as a transfer to the hospital association; and be it further

Resolved, That any new hospital standardization program be a joint venture whereby the medical components of the plan would set medical practice standards and the administrative components would set non medical standards, each group having representation on the board which will be the final authority.

Report of Reference Committee on Medical Education

The Reference Committee on Medical Education, to which the resolutions were referred, presented the following report, which was adopted:

Your committee gave serious consideration to the resolutions presented by Dr. James Z. Appel on the subject of hospital standardization Your committee agrees with the principles expressed in the resolution but because of the study being given to this matter at the present time, your committee feels that no action should be taken

Resolution on Mail Deliveries

Dr James Z. Appel, Pennsylvania, presented the following resolution:

Whereas, The present restricted schedule of first class mail deliveries and collections has resulted in serious inconvenience to the public; and

Whereas, This situation has been a particular hardship to physicians in the performance of their important professional duties; therefore be it

Resolved, That the House of Delegates of the American Medical Association go on record as strongly urging the prompt restoration of previous first class delivery and collection schedules in the Post Office Department

Report of Reference Committee on Miscellaneous Business

The Reference Committee on Miscellaneous Business presented the following report, which was adopted:

Your Committee on Miscellaneous Business is in sympathy with the intent of the resolution but feels that this is not pertinent to the affairs of the House of Delegates of the American Medical Association It, therefore, recommends that this resolution not be adopted.

Resolution on Absence of Dr. Roy Fouts

Dr. James Z. Appel, Pennsylvania, submitted the following resolution, which was adopted:

Whereas, Dr. Roy Fouts, a member of this House of Delegates for 28 years, during which time he most ably served as Vice Speaker and Speaker of the House of Delegates, is unable to attend this session due to illness; be it

Resolved, That the House of Delegates express its sincere hope for his speedy recovery and inform him that his absence from this session has created a definite loss to the American Medical Association

Resolution on Proposed Amendment to Principles of Medical Ethics

Dr Allen T. Stewart, Texas, presented the following resolution proposing an amendment to the Principles of Medical Ethics:

Whereas, On June 6, 1949, at the recommendation of the Judicial Council, the House of Delegates of the American Medical Association approved a revision of the Principles of Medical Ethics, and

Whereas, In Section 6, Chapter I of these revised Principles of Medical Ethics there are two sentences which read "An ethical physician does not engage in barter or trade in the appliances, devices or remedies prescribed for patients, but limits the sources of his professional income to professional services rendered the patient He should receive his remuneration for professional services rendered only in the amount of his fee specifically announced to his patient at the time the service is rendered or in the form of a subsequent statement, and he should not accept additional compensation secretly or openly, directly or indirectly, from any other source", and

Whereas, An interpretation of these sentences by the Judicial Council classifies as unethical many accepted practices of physicians, necessary for the proper care and protection of their patients, particularly in rural areas and in smaller communities; and

Whereas, A code of ethics should be so worded as to be reasonable and susceptible of universal application to all members of the society, irrespective of the size or location of their community; and

Whereas, The enforcement of this provision of the Principles of Medical Ethics would be a restrictive infringement on the freedom of physicians to indulge in many legitimate businesses related to their profession, and

Whereas, The Federal Government is using these sentences as an entering wedge to restrict and legally control the independent and nonprofessional business activities of the members of the medical profession thereby depriving them of their constitutional rights to private enterprise; and

Whereas, The disregarding of this provision of the Principles of Medical Ethics would provide opportunities for charges of hypocrisy, evasion and subterfuge against the medical profession, as it is well known that many reputable physicians have interests or stocks in enterprises connected with the medical profession, which ownerships and interests are considered entirely proper by the profession and community as a whole, but which would be outlawed and declared unethical by the application of the provisions of these sentences in Section 6, Chapter I; and

Whereas, It has always been the policy of the American Medical Association, acting through its House of Delegates, to be unalterably opposed to rebating in any form; therefore be it

Resolved, That the House of Delegates of the American Medical Association delete the fourth and fifth sentences of Section 6, Chapter I, Principles of Medical Ethics, leaving the section to read "An ethical physician will not receive remuneration from patents on or the sale of surgical instruments, appliances and medicines nor profit from a copyright on methods or procedures The receipt of remuneration from patents or copyrights tempts the owners thereof to retard or inhibit research or to restrict the benefits derivable therefrom to patients, the public or the medical profession The acceptance of rebates on prescriptions or appliances, or of commissions from attendants who aid in the care of patients is unethical The prescription or dispensing by a physician of secret medicines or other secret remedial agents, of which he does not know the composition, or the manufacture or promotion of their use is unethical"

Report of Reference Committee on Miscellaneous Business

The Reference Committee on Miscellaneous Business submitted the following report, which was adopted:

1. Resolution on "Amendment of Principles of Medical Ethics, Sec 6, Ch I": Your Reference Committee on Miscellaneous Business after a full hearing and much discussion before the committee of the various problems of medical practice pertinent to this resolution and realizing the difficulty of immediate solution, recommends that this resolution be referred to the Judicial Council with the suggestion by the committee that in Chapter I, Section 6, the fourth sentence, the words, "for financial gain" be inserted after the words, "for patients," and that the remainder of the paragraph be deleted Because of the suggested reference of this resolution to the Judicial Council with the foregoing suggestions by the committee it recommends that the resolution as presented be not approved and that the suggestions be referred to the Judicial Council

Resolutions on Establishment of Special Committee on the Problems of Alcoholism

Dr H. H. Bauckus, New York, presented the following resolutions:

Whereas, At the Ninety Ninth Annual Session of the House of Delegates of the American Medical Association, a resolution was introduced by Dr Joseph P Henry of New York on the Establishment of a Committee on the Problems of Alcoholism, as described on page 40 of the Proceedings of that Session, and

Whereas, The resolution was referred to the Reference Committee on Miscellaneous Business, and

Whereas, The said reference committee reported back to the House of Delegates, as shown on page 55 of the Proceedings, paragraph 6, that the subject should be studied by "the already established Commission on Chronic Illness", and

Whereas, The said commission is not the proper body to whom this subject should be delegated because it is not a committee of the American Medical Association, now therefore be it

Resolved, By the House of Delegates of the American Medical Association, that the reference to the Commission on Chronic Illness be, and it hereby is, rescinded, and be it further

Resolved, That the same resolution presented by Dr. Joseph P Henry of New York at the Ninety Ninth Annual Session of the House of Delegates be reenacted by this body, as follows:

"*Resolved,* That the American Medical Association establish at the earliest feasible date a special committee on the problems of alcoholism, to formulate and put into effect, on a nationwide basis, a comprehensive and effective program for medicine's aggressive participation in the work of solving the problems of alcoholism, such program to include a vigorous recommendation to each constituent state and component county medical society that it establish and support actively a special committee patterned after the special committee on the problems of alcoholism of the Medical Society of the State of New York."

Report of Reference Committee on Hygiene and Public Health

These resolutions were referred to the Reference Committee on Hygiene and Public Health, which submitted the following report and its report was adopted:

Your Reference Committee on Hygiene and Public Health agrees with the intent of these resolutions. It believes reference of the original resolution presented at San Francisco for implementation to the Commission on Chronic Illness was unwise. Inasmuch as the establishment of new special committees is considered undesirable, and after consultation with the sponsors of the resolution and the chairman of the Committee on Chronic Diseases, your reference committee recommends that the problems of alcoholism be referred to the Committee on Chronic Diseases for study and implementation.

Resolution on Federal Aid to Medical Education

Dr. Laurence S. Nelson Sr., Kansas, presented the following resolution:

Whereas, Federal support of any program whatever has inevitably resulted in the regulation and increasing control over that program; and

Whereas, Federal funds represent taxes raised at state and local levels, only a portion of which are ultimately returned to the project at local levels; and

Whereas, Examples exist of successful state and local support of medical schools as in Kansas, rendering further aid at federal levels unnecessary; and

Whereas, The Kansas effort was accomplished through the active participation of the people of Kansas, acting on their own initiative to solve their problems; and

Whereas, This can be accomplished elsewhere through the cooperative effort of the medical school, the medical profession and the people of the state; and

Whereas, Federal grants to research must be considered entirely apart from federal aid to medical education since the results of these researches serve a nationwide and even international effect on medical care and health problems; therefore be it

Resolved, That opposition to federal legislation for the appropriation of financial aid to medical schools be vigorously continued and that increasing effort be expended toward the local solution of financial problems confronting the schools of medicine in this nation.

Report of Reference Committee on Medical Education

The Reference Committee on Medical Education, to which the resolution was referred submitted the following report which was adopted:

Your reference committee considered the resolution presented by the Kansas Medical Society pertaining to federal aid for medical education. Your committee agrees with the principles expressed in this resolution that the financing of medical education should be done on a local level where possible but since this matter has previously been covered in "A Joint Statement by the Board of Trustees and the Council on Medical Education and Hospitals of the American Medical Association on Senate Bill 1453 and H. R. 5940," your committee offers the following substitute resolution:

Resolved, That while some medical schools are finding it difficult to secure sufficient funds to maintain their standards of training, the American Medical Association would prefer to see medical schools receive the support they require from private philanthropy or local public funds. Unless and until such support is provided, it may be necessary for some medical schools to accept financial aid from the federal government. Such aid, however, must carry with it the assurance of freedom from political control and regulation.

Resolution on Inspection of Government Agencies and the Use of Medical Personnel

Dr. E. F. Hoffman, California, presented the following resolution:

Whereas, Because of the international situation and because the administration in its drive to socialize medicine is no longer trustworthy, it has become necessary for the medical profession, in the interest of the public welfare, to inspect and control the use of medical personnel by the military and other government agencies; and

Whereas, The medical profession through the American Medical Association is responsible for the medical care of military and civilian population; and

Whereas, In such matters as medical legislation and relations with military and government agencies, the medical profession has demonstrated its unselfish patriotism; and

Whereas, In the past the military has been reckless in the call-up of doctors and wasteful in their use; and

Whereas, During peacetime, immediately following the last war, physicians were ordered to duty by the military to serve in nonmilitary government agencies, such as Veterans Administration, Public Health and Indian Service; and

Whereas, This dangerous policy of conscription of doctors for civilian purposes in peacetime was one of the direct causes of the present doctor draft law; and

Whereas, There is the constant tendency for military hospitals to expand and take on civilian practice; and

Whereas, The precedent of inspection of military and other government hospitals has already been established by civilian specialty boards for purposes of certification; therefore be it

Resolved, That the American Medical Association establish an advisory committee with the express function of inspecting all government agencies, military and civilian, here and abroad, to see that drafted medical personnel are not wasted and are not used to staff civilian government agencies in competition with private physicians and hospitals.

Report of Reference Committee on Emergency Medical Service

The Reference Committee on Emergency Medical Service, to which the resolution was referred, offered the following report which was adopted:

The committee is in agreement with the intent of this resolution that every possible means be taken to avoid waste of medical personnel in the armed forces. At the committee hearing its consulting members, representing the various branches of the armed forces, discussed this question very fully. As a result of these discussions, your committee now finds that this problem has been receiving their serious consideration and is being solved as promptly as possible. Furthermore, an Office of Medical Services, headed by a civilian physician, was established in the Office of the Secretary of Defense some time ago. Furthermore, the Council on National Emergency Medical Service has reported that an Advisory Committee, composed of outstanding members of the civilian health professions and including two members of its Council, has recently been appointed to advise the Chairman of the National Security Resources Board on the proper allocation of the health resources of the nation, including the medical profession, in the event of full scale mobilization.

In view, therefore, of all the necessary steps now being taken to conserve our medical personnel in both the armed forces and in civilian life, your committee feels that any action by the House of Delegates on this resolution is unnecessary.

Resolutions on Competition with Practice of Medicine

Dr. George M. Fister, Utah, presented the following resolutions:

Whereas, There is a well recognized growing tendency on the part of administrators of many hospitals to encourage private ambulatory patients to enter the radiological, pathological and physical therapy departments of their institutions for the purpose of examination and treatment; and

Whereas, This practice tends to put such hospitals into competition with physicians who are engaged in the private practice of their specialties; and

Whereas, The House of Delegates of the Utah State Medical Association is on record as disapproving the proselyting of private ambulatory patients by hospitals for the purpose of making studies or giving treatments in various departments of such hospitals; therefore be it

Resolved, That the House of Delegates of the American Medical Association go on record as approving in principle of this action of the Utah State Medical Association; and be it further

Resolved, That the House of Delegates of the American Medical Association instruct the proper councils of that body to take the necessary action to carry out the intent of these resolutions.

Report of Reference Committee on Medical Education

The following report which was adopted, was presented by the Reference Committee on Medical Education:

After consideration of the resolutions presented by the Utah State Medical Association regarding competition with the practice of medicine, your committee was in general agreement with the principles set forth in these resolutions but since policy has already been established by the adoption of the Hess committee report, the committee believes that no action is necessary and directs attention to the report of the Judicial Council which outlines the mechanism by which the problem can be solved.

Resolutions on Fund for Aid to Medical Schools

Dr. Edward H. McLean, Oregon, submitted the following resolutions:

Whereas, Medical graduates, even though they have paid full tuition, contribute only 25 *to 50 per cent of the cost of their education and* therefore owe a moral debt to their medical school; and

Whereas, Many medical graduates recognize this moral debt and would be glad to discharge it in part after they become well established in practice, and

Whereas, Federal subsidy of medical education has been vigorously sought by the social planners as one phase in their over all promotion of the socialization of medicine; and

Whereas, Federal subsidy inevitably involves political control, which would lead to a deterioration in teaching standards; and

Whereas, The National Fund for Medical Education Inc has recently been organized to support medical education in the United States on a voluntary basis; and

Whereas, The American Medical Association can play a useful role in the voluntary movement for the support of American medical education by establishing means by which its members can discharge the moral debt arising from their professional education; therefore be it

Resolved, That the House of Delegates of the American Medical Association recognizes the moral debt of the medical profession to the medical schools; and be it further

Resolved, That the House of Delegates instruct the Board of Trustees to study the feasibility of establishing a fund for aid to medical schools to be created by voluntary subscriptions or by allotments from annual dues, said fund to be administered by the Board of Trustees or contributed to the National Fund for Medical Education Inc.

Report of Reference Committee on Medical Education

The Reference Committee on Medical Education, to which the resolutions were referred, presented the following report, which was adopted:

Your reference committee has given careful consideration to the resolutions presented by the Oregon State Medical Society with regard to the feasibility of establishing a fund for aid to medical schools to be created by voluntary subscriptions or by allotments from annual dues and recommends their adoption.

Resolution on Amendment to By-Laws

Dr. C. L. Farrell, Rhode Island, submitted the following resolution recommending an amendment to Division Three Chapter IX, Section 1, (B) and (C)

Whereas, The scope of the work of the individual members of the House of Delegates of the American Medical Association has increased greatly in recent years, thereby making satisfactory representation of a constituent association by a single delegate almost impossible; and

Whereas, There are twenty state and territorial associations faced with this serious problem of having but a single representative to inform them of the many actions of the House and its reference committees; and

Whereas, It is vital today that each state association be adequately represented in the formation of national policies of the American Medical Association, and in turn be completely informed of the transaction of all business of the Association; therefore be it

Resolved, That the Rhode Island Medical Society, by action of its House of Delegates in meeting on September 27, 1950, request the House of Delegates of the American Medical Association to amend Chapter IX, Sec. 1 (B) and (C) of its By Laws to read as follows.

Section 1.

(B) Term—Delegates and alternates from constituent associations, sections, the United States Army, the United States Navy, the United States Air Force, the United States Public Health Service and the Veterans Administration shall be elected or appointed, as the case may be, for two year terms, and shall assume office on January 1 of the year succeeding their election or appointment except that incumbent delegates on the date of the adoption of these By Laws shall serve until their successors are elected and assume office Constituent associations entitled to more than two representatives shall elect them so that one half the number, as near as may be, are elected each year.

Secretaries of constituent associations, secretaries of sections of the Scientific Assembly, the Surgeons General of the United States Army, the United States Navy and the United States Public Health Service and the Chief Medical Director of the Veterans Administration shall certify delegates and alternates to the Secretary of the American Medical Association

(C) Apportionment—The apportionment of delegates from each constituent state association shall be one delegate for each thousand (1,000) active members or fraction thereof where the membership exceeds one thousand, and shall be two delegates for each state with one thousand (1,000) or less active members, as recorded in the office of the Secretary of the American Medical Association on December 1 of each year. Such apportionment shall take effect the ensuing January 1 and shall remain effective for one year thereafter. In December of each year the Secretary of the American Medical Association shall notify each constituent association of the number of delegates to which it is entitled during the next succeeding year

Report of Reference Committee on Amendments to the Constitution and By-Laws

The Reference Committee on Amendments to the Constitution and By-Laws, to which the resolution was referred offered the following report, which was adopted:

A resolution received by your committee came from the Rhode Island Medical Society and dealt with the number of delegates in those constituent associations which have 1,000 or fewer members Your committee realizes the difficulties which are encountered in those constituent associations which are limited to one delegate in the House of Delegates On the other hand, it also realizes that the adoption of such an amendment would give the physicians in these small associations a much larger voice proportionately in the House of Delegates than would be possessed by the larger delegations Your committee, after full hearings and discussion, recommends that this resolution be not adopted, but that the problem of the difficulties of the small constituent associations be referred to the permanent Committee on Amendments to the Constitution and By-Laws for study. Your committee would also request that the permanent Committee on Constitution and By-Laws consider the problem of the single representative from a constituent association who becomes ill or who is called home after being seated in the House of Delegates. See By-Laws, Division Three, Chapter IX, Section 1 (E).

In the hearings held before the committee and in the deliberation itself, it became evident that there is a diversity of opinion as to just what is meant by the terms "ex officio," "ex officio without power to vote" and "executive session" Your committee would recommend that this matter be referred to the permanent Committee on Constitution and By-Laws for interpretation and clarification, with instructions to make a report on this matter at the next session of the House of Delegates.

Proposed Amendment to Constitution

Dr. James P. Wall, Mississippi, presented the following proposed Amendment to the Constitution, Article 6, Section 2:

Amend Article 6, Section 2 so that beginning after the word "service" add: "and the Past Presidents of the American Medical Association" and in the last sentence the following phrase should be deleted: "the Past Presidents." So amended, Article 6 Section 2 would read:

"The House of Delegates is composed of delegates duly elected by the constituent associations and by the sections of the Scientific Assembly and of delegates from the Medical Departments of the United States Army, the United States Navy, the United States Air Force, the United States Public Health Service and the Veterans Administration, appointed by the Surgeon General or Chief Medical Director, as the case may be, of the respective service, and the Past Presidents of the American Medical Association. The general officers, the General Manager, the Editor of The Journal of the American Medical Association and the chairmen of the several Councils shall be ex officio members of the House of Delegates without the right to vote."

Proposed Amendment to the By-Laws

Dr. Wall also presented the following proposed amendment to the By-Laws, Division Three, Chapter IX, Section 1 (B):

Amend Division Three, Chapter IX, Section 1 (B), beginning after the sentence ending "are elected each year", add: Past Presidents of the American Medical Association shall serve for a period of five years immediately following their tenure of the Presidency of the American Medical Association

So amended, that portion of the By-Laws would read as follows: The delegates and alternates from constituent associations, sections, the United States Army, the United States Navy, the United States Air Force, the United States Public Health Service and the Veterans Administration shall be elected or appointed, as the case may be, for two year terms and shall assume office on January 1 of the year succeeding their election or appointment except that incumbent delegates on the date of the adoption of these By-Laws shall serve until their successors are elected and assume office. Constituent associations entitled to more than one representative shall elect them so that one half the number, as near as may be, are elected each year. Past Presidents of the American Medical

Association shall serve for a period of five years immediately following their tenure of the Presidency of the American Medical Association.

REPORT OF REFERENCE COMMITTEE ON AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

These proposed amendments to the Constitution and the By-Laws were referred to the Reference Committee on Amendments to the Constitution and By-Laws, which reported as follows and the report was adopted:

Your committee received proposed amendments from Dr. James P. Wall, Mississippi, relative to past presidents serving in the House of Delegates Your committee spent considerable time in hearing arguments for and against these amendments and in its own deliberations. Your committee is of the unanimous opinion that the best interests of the Association would not be served by the adoption of these amendments. Your committee therefore recommends that the proposed amendments to the Constitution and By-Laws as presented by Dr. Wall be not adopted.

Resolutions on Medical and Hospital Care of Veterans with Nonservice Connected Disabilities

Dr. Robert B. Wood, Tennessee, presented the following resolutions, which were supported by Drs. Wyman D. Barrett, Michigan, S. E. Gavin, Wisconsin, and James Q. Graves, Louisiana:

WHEREAS, The present program of medical and hospital benefits for veterans with nonservice connected disabilities is of unequal benefit to veterans and not universally available to all eligible veterans because of the presently limited facilities; and

WHEREAS, The program of expanding the number and size of veterans' hospitals to the point of making these benefits reasonably available and accessible to all veterans, especially in cases of acute illness or injury, would require the construction and administration of a very large number of veterans' hospitals, and

WHEREAS, The principle of insurance has been proved by experience to be applicable to the financing of the cost of medical and hospital care; now, therefore, be it

Resolved, By the House of Delegates of the American Medical Association that we recommend to the Congress of the United States and to veterans the enactment of legislation which would have the following effect The repeal of Section 706, Chapter 12, Title 38, of the World War Veterans' Act (Reference, U. S Code, 1940 Edition) and the enactment of a new law with provisions which require the Administrator of Veterans' Affairs to make available to veterans who are unable to pay for their hospital and medical services, hospital and medical service benefits in the form of a hospital and medical service insurance contract, and that the Administrator of Veterans' Affairs be authorized to use his discretion in providing such insurance coverage, either (1) by furnishing each eligible veteran an amount of money sufficient to cover the premium cost of such an insurance contract (about $40 per year), or (2) by purchasing the coverage on behalf of eligible veterans from a corporation or corporations selling and administering such insurance coverage, and be it further

Resolved, That the benefit provision of such a contract be sufficient to cover (1) the average cost of hospital service in approved general hospitals, and (2) medical and surgical services rendered in such a hospital on the basis of the fee schedule that applies to veterans with service-connected disabilities; and be it further

Resolved, That such contracts cover all diseases and disabilities which require hospitalization except (1) disabilities covered by compensation laws and public liability, (2) service connected disabilities, (3) chronic illness (extending over 90 days), (4) tuberculosis and (5) mental illness, and be it further

Resolved, That veterans with disabilities in the categories mentioned in the preceding paragraph, excepting those covered by compensation laws and public liability, be eligible for admission to Veterans' Hospitals; and be it further

Resolved, That veterans with disabilities which are in dispute as to whether or not they are service connected be eligible for admission to Veterans' Hospitals for study, treatment, and adjudication, and that the disability then be classified for these benefits according to the judgment rendered, and be it further

Resolved, That the eligibility of a veteran to receive the insurance contract mentioned above be determined on the basis of his or her net income as determined for federal income tax purposes, and that only veterans who are not liable for a federal income tax be eligible for the hospital and medical insurance contract above referred to, and be it further

Resolved, That the veteran be required to file an application for the insurance contract on a form prescribed by the Administrator of Veterans' Affairs, in which the veteran states under oath the pertinent facts concerning his or her liability for a federal income tax, and be it further

Resolved, That the Coordination Committee on Legislation of the American Medical Association be instructed to use its best efforts to secure congressional action in harmony with the proposals in these resolutions

REPORT OF REFERENCE COMMITTEE ON INSURANCE AND MEDICAL SERVICE

The report of the Reference Committee on Insurance and Medical Service, to which the resolutions were referred, and which was adopted, reads as follows:

On the subject of the resolutions relating to the medical and hospital care of veterans with nonservice connected disabilities sponsored by the delegation from Tennessee and supported by delegates from Michigan, Wisconsin and Louisiana, the committee heard the most witnesses and spent the most time

A substitute resolution presented to the committee by the Pennsylvania delegation was also considered Instead of the language of either of these proposals the reference committee recommends to the House that the Board of Trustees be authorized to permit the Committee on Legislation of the American Medical Association to offer its services to the authorities of the Veterans Administration or to the Congress in seeking either administrative or legislative support for the following three principles. (1) The best possible care of all veterans with service-connected disabilities in Veterans Administration facilities; (2) the best possible care of veterans with nonservice connected disabilities who need financial support, and (3) veterans with nonservice connected disabilities who are able to do so should provide their own care

Resolution on Change in Name of Section on Nervous and Mental Diseases

Dr. Percival Bailey, Section on Nervous and Mental Diseases, presented the following resolution:

WHEREAS, The term Nervous and Mental Diseases has become obsolete, and

WHEREAS, The terms Neurology and Psychiatry are well established and generally understood; and

WHEREAS, The Section on Nervous and Mental Diseases has already been referred to erroneously in THE JOURNAL as the Section on Neurology and Psychiatry; now therefore be it

Resolved, That the House of Delegates of the Association authorize the Section on Nervous and Mental Diseases to change its name to the Section on Neurology and Psychiatry.

REPORT OF REFERENCE COMMITTEE ON SECTIONS AND SECTION WORK

This resolution was referred to the Reference Committee on Sections and Section Work, which presented the following report which was adopted:

Your reference committee, after due consideration, recommends that this resolution be disapproved

Resolution on Payment of Expenses of Section Delegates

Dr. Percival Bailey, Section on Nervous and Mental Diseases, presented the following resolution:

WHEREAS, The sections of the Scientific Assembly have no funds of their own with which to pay the expenses of their delegates, and

WHEREAS, The expenses of the delegates of most state associations are now paid by the organizations which they represent; and

WHEREAS, The number of meetings annually which the delegates have to attend has doubled, thus doubling their expenses, and

WHEREAS, The Section on Nervous and Mental Diseases fears that this will make it difficult to secure the sort of representation in the House of Delegates which it desires, therefore be it

Resolved, That the Board of Trustees be requested to make provision for the payment of the expenses of the delegates of the sections from the general funds of the Association

REPORT OF REFERENCE COMMITTEE ON REPORTS OF BOARD OF TRUSTEES AND SECRETARY

This resolution was finally referred to the Reference Committee on Reports of Board of Trustees and Secretary, which reported as follows and the report was adopted:

Since a new resolution was introduced at this session by Dr. Percival Bailey, Section on Nervous and Mental Diseases, relating to this matter, both the report of the Board and the resolution were considered by your committee at the same time The Board of Trustees has already taken action on this matter and it is the opinion of your committee that the Board took the only practical course in denying the requested appropriations

Resolution on Hospital Standardization

Dr. J. B. Copeland, Texas, presented the following resolution

WHEREAS, The Board of Regents of the American College of Surgeons has entered into discussions with the American Hospital Association concerning the transfer of the hospital standardization program of the American College of Surgeons to the American Hospital Association, and

WHEREAS, Pursuant to these negotiations, even though the American College of Surgeons has stated it will continue its former program, the house of delegates of the American Hospital Association at its annual meeting in Atlantic City in September passed a resolution increasing the dues of the Association to finance a program in hospital standardization and instructed its board of trustees to proceed forthwith to take over the inspection and standardization of hospitals, and

Whereas, The evaluation of medical standards in hospitals is not a proper function for the American Hospital Association, the governing members of which are predominantly laymen; and

Whereas, The proper and logical body to assume sole and complete control of the evaluation and standardization of medical practice in hospitals is the American Medical Association, therefore be it

Resolved, That the House of Delegates of the American Medical Association reaffirms the proposal stated in a report by a special committee to study conditions of general practice, adopted by this House of Delegates at the annual session in 1948, in which it was recommended that the sole responsibility for the evaluation and standardization of medical practice in hospitals be vested in the Council on Medical Education and Hospitals of the American Medical Association

Report of Reference Committee on Medical Education

The Reference Committee on Medical Education submitted the following report which was adopted:

Hearings on this resolution were held and many members, Fellows, officers, representatives of the American Academy of General Practice and other interested persons discussed the subject at length. After much deliberation by the members of the committee, and in consideration of previous action by the House of Delegates taken in reference to this matter, especially at the 1948 meeting of the House of Delegates as indicated in the report of the Committee to Study Conditions of General Practice and subsequent action of the House of Delegates in 1949 when the action of 1948 was amended as follows and approved:

Resolved, That the American Medical Association highly commends the American College of Surgeons for its long sustained efforts in the field of hospital standardization and endorses its continued activity in this important field; and be it further

Resolved, That the Secretary of the American Medical Association transmit a copy of these resolutions to the Board of Regents of the American College of Surgeons.

In view of the fact that we have just agreed to a further study of this problem, your reference committee recommends that this resolution be not approved.

Resolution on Proposed Amendment to By-Laws, Division Three, Chapter XIII, Section 1

Dr. W. R. Brooksher, Arkansas, presented the following resolution recommending amendment to Division Three, Chapter XIII, Section 1 of the By-Laws:

Whereas, The President and the President Elect of the American Medical Association are the chosen leaders of the organization and as such should be given a voice in formulating its policies; and

Whereas, In most medical organizations the President and the President Elect are full members of the executive governing body; and

Whereas, Under our present Constitution and By-Laws, the President and President Elect are privileged to attend the meetings of the Board of Trustees but are not members of that body, therefore be it

Resolved, That Division Three, Chapter XIII, Section 1, of the By Laws of the American Medical Association be amended as follows:

"Composition—The Board of Trustees shall consist of nine elected Trustees as provided in Article 7 of the Constitution, the President and the President Elect. The Vice President, the Secretary, the Treasurer, the Speaker, the Vice Speaker, the General Manager and the Editor of The Journal may attend meetings of the Board.

Report of Reference Committee on Amendments to Constitution and By-Laws

The Reference Committee on Amendments to the Constitution and By-Laws reported on this resolution as follows, and its report was adopted:

Your committee received a resolution from Dr. W. R. Brooksher of Arkansas with an amendment which would make the President and the President-Elect members of the Board of Trustees. Your committee is not certain as to whether such an amendment could be adopted without a complementary amendment to the constitution and by-laws, nor does your committee know whether an increase in the number of members of the Board of Trustees could be made under the laws of the charter under which the American Medical Association operates, nor is your committee of one mind as to whether the best purposes of the Association could be served by the adoption of this amendment. Your committee recommends, therefore, that this proposed amendment be referred to the permanent Committee on Constitution and By-Laws for further study.

Resolution on Federal Department of Health

Dr. Bruce Underwood, Kentucky, presented the following resolution:

Whereas, The health activities now being carried on by agencies of the Federal Government are of great importance to the citizens of the nation; and

Whereas, There are great differences in the administrative and professional technics required in the execution of health activities as distinguished from welfare, education and other activities of the federal government; and

Whereas, The practicability, success and desirability of the administration of health activities in a separate and distinct health agency has been demonstrated in the states; and

Whereas, The members of the American Medical Association have a keen interest in, and are vitally concerned by, the administrative relationships and administration standing of the federal health agencies, therefore be it

Resolved, That the House of Delegates of the American Medical Association urges all officers and members of the American Medical Association and all component associations to take immediate steps to implement the passage into law of a bill providing for: (1) a Federal Department of Health of cabinet status with a secretary who is a Doctor of Medicine and who has had special training and experience to qualify him for the position; (2) the coordination and integration of all federal health activities under this department except for the military activities of the medical services of the armed forces; (3) a Federal Board of Health under professional rather than political control whose duties shall be to appoint the Secretary of Health and to establish the policies under which the Federal Department of Health is operated.

Report of Reference Committee on Legislation and Public Relations

The Reference Committee on Legislation and Public Relations presented the following report, which was adopted:

Your Reference Committee on Legislation and Public Relations considered the resolution as presented by the Kentucky delegation regarding the establishment of a federal department of health with Cabinet status. Considerable testimony and deliberation by various officers, delegates and members of the Association led this committee to reach the conclusion that such a department with Cabinet rank would be unattainable at this time. It appears to this committee that the same results will or can be achieved by the establishment of an independent agency with executive status in which all of the federal health activities are coordinated All federal health activities except those of the armed forces and the Veterans Administration should be separated from other functions of the government such as welfare and education. This in no manner reverses the well established stated policy of the Association with respect to a federal department of health inasmuch as that objective would be achieved by the adoption of this proposed action. Your reference committee would therefore offer the following substitute resolution:

Resolved, That the House of Delegates of the American Medical Association urges all officers and members of the American Medical Association and all constituent associations to take immediate steps to implement the passage into law of a bill providing for the coordination and integration of all federal health activities under an independent agency with executive status, except the medical services of the Armed Forces and of the Veterans Administration

Resolution on Determining Policy of American Medical Association on Legislative Proposal

Dr. Hoyt B. Woolley, Idaho, submitted the following resolution:

Whereas, On numerous occasions the House of Delegates is not in session at the time many legislative proposals are being considered by Congress or committees of Congress; and

Whereas, The Board of Trustees is the proper body to determine the policy on legislative proposals during the time that the House of Delegates is not in session; and

Whereas, The House of Delegates of the American Medical Association, having full confidence in its Board of Trustees and in the committees appointed by the Board of Trustees to represent the American Medical Association before the national bodies of Congress and other groups where it is necessary to state the policy of the American Medical Association; now therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby specifically authorizes the Board of Trustees and the persons designated by them to appear as witnesses before committees of Congress or to appear before other groups where the policy of the American Medical Association is to be stated, and to do so with full authority to speak for and state the policy of the American Medical Association

REPORT OF REFERENCE COMMITTEE ON LEGISLATION AND PUBLIC RELATIONS

The resolution was referred to the Reference Committee on Legislation and Public Relations, which presented the following report which was adopted:

The Committee agrees that representatives of the American Medical Association appearing before Congress and other groups should do so with full authority to speak for and state the policy of the American Medical Association and its House of Delegates. It recommends the adoption of this resolution.

Report of Committee on Chronic Diseases

Dr. Robertson Ward, Chairman, presented the following report, which was adopted:

Your committee had a profitable meeting on Dec. 4, 1950, with representatives of the United States Public Health Service, including the director of the Chronic Disease Division, Dr. A. L. Chapman. Also represented by its director, Dr. Morton I. Levin, was the Commission on Chronic Illness. The committee would like to repeat its request of last June for the addition to it of a member of the House of Delegates who is also a member of the Commission on Chronic Illness, in order that better liaison between the committee and the commission could be maintained.

From the meeting with members of the United States Public Health Service and the information furnished by them, a better understanding of the aims and objectives of the Public Health Service in the field of chronic disease was obtained. Through the printed material furnished the committee and the statements of the Director of the Division of Chronic Diseases of the United States Public Health Service, it was learned that his department, rather than seeking a large categorical appropriation, will endeavor to perform an integrative function. It was further understood by your committee that the primary objective of the Division is to evolve and test methods for controlling the chronic diseases in such a way that their efforts will not be competitive with the activities and interest of private physicians, but will be supplementary to them. Nothing could be more satisfying to your committee than strict adherence to these principles by the United States Public Health Service.

The activities of the Chronic Disease Division are divided into four categories, namely, prevention, case finding, care and restorative services. To date most of the energies of the division have been devoted to case finding, principally by means of multiphasic screening examinations. It is generally admitted that this type of examination is undergoing evaluation as a reliable technic for case finding. For this reason, your committee strongly urges those conducting such examinations to use the utmost discretion in reporting results. It is further urged that every effort be made to inform the individuals undergoing the screening process that it in no way serves as a substitute for careful periodic medical examinations. Every possible advertising device should be employed to impress this on those screened. In this connection your committee would like to call your attention to that part of the report of the Council on Industrial Health, delineating the safeguards for multiphasic screening operations.

One of the objectives of the Commission on Chronic Illness, as reported to you by this committee last June, was to stimulate in every state and locality a well rounded plan for prevention and control of chronic disease and for the care and rehabilitation of the chronically ill. It is the belief of your committee that an important step in the implementation of this objective would be the creation in each state medical association of chronic disease committees. We are informed by Dr. Levin that such committees are in existence in only 10 states at the present time. We feel that to be effective, such a committee should be composed of strong personnel who are definitely interested in chronic disease and who would be able to impress the private physician with his continuing responsibility for the care and rehabilitation of patients with chronic diseases, and for the development of sound principles of healthful living for the older-age group of the population.

Your committee cannot close this report without calling to your attention the fact that the Chronic Disease Division is only one agency in the United States Public Health Service having an interest in the problem of chronic diseases. Actually, by far the greatest proportion of federal expenditures for research and education in this field is by other agencies such as the National Institute of Mental Health, the National Heart Institute and the National Cancer Institute. For example, whereas the budget of the Chronic Disease Division is in the neighborhood of $2,000,000 annually, the budget of the National Heart Institute alone is more than nine and a half million dollars. Your committee feels that a more critical analysis of all expenditures in the chronic disease field should be prepared for you. For this reason, it is recommended that the committee be continued and furnished appropriate and adequate assistance.

Supplementary Report of Board of Trustees on Fund for Aid of Medical Schools

Dr. Louis H. Bauer, Chairman, Board of Trustees, presented the following action of the Board on Fund for Aid of Medical Schools, which was adopted on motion of Dr. B. O. Edwards, North Carolina, seconded by several and carried unanimously:

The Board of Trustees of the American Medical Association is pleased to announce to the House of Delegates that it has appropriated a half million dollars out of its National Education Campaign Fund, which was raised to defend medical freedom, for the aid and support of medical schools which are in need of additional financing.

This fund will be given to the medical schools for their unrestricted use in their basic training of future physicians.

This appropriation to aid the medical schools has been made possible by the widespread public cooperation which the profession has received from the American people in its campaign against compulsory health insurance. The fight against socialized medicine must go on until this issue has been clearly and finally resolved, but the pressure for regimentation of the medical profession has greatly lessened due to the magnificent public support which we have received.

The Board of Trustees, therefore, feels that it is keeping faith with the American people, who have given medicine such a splendid vote of confidence, when it contributes this amount to the medical schools of the nation.

There is growing public awareness that federal subsidy has come to be a burden, not a bounty, for it is bringing intolerable increases in taxation and is dangerously increasing federal controls over our institutions and the lives of our people.

American medicine feels very strongly that it should not seek federal aid for medical schools until all other means of financing have been exhausted. The Board of Trustees announced yesterday its belief that funds for this purpose could be obtained from private sources and, as practical evidence of our sincerity of purpose, this appropriation has been made as the nucleus of a fund which we hope will be greatly augmented by contributions from many other sources.

The Board hopes that this action will become a stimulus to other professions, industries, businesses, labor groups and private donors to contribute to this very important cause of protecting and advancing the interests of medical education and the public health.

The American Medical Association urges all its members to contribute individually to this cause, and we hope that doctors will take the lead in securing contributions from other sources.

Furthermore, the American Medical Association invites attention to the fact that it has been spending about a quarter of a million dollars a year for many years past to advance medical education through its Council on Medical Education and Hospitals and other departments. This appropriation, voted today, for an entirely new purpose, is in addition to nearly $285,000 already budgeted for this work during 1951.

The nation's medical schools are of the greatest importance to every American citizen and the American Medical Association has had the advancement of their standards as one of its main objectives for over 100 years. The Board of Trustees feels that if all other organizations and individuals will render support to this worthy cause in accordance with their financial ability not only will the financial security of medical schools be assured, but their freedom will be protected.

WASHINGTON NEWS

(From the Washington Office of the American Medical Association)

Civil Defense

The attitude of Senate and House committees considering Civil Defense Administration bills indicates relatively fast passage, but with important amendments. The net effect, according to present trends, will be to modify powers of the proposed administration, yet allow it adequate freedom for action in emergencies. For one thing, the Federal Bureau of Investigation has complained that the bill as written would give the administration certain investigative powers ordinarily reserved for the FBI. The FBI probably will be allowed to have its way on this point. Some questions have been raised as to the advisability of nationwide construction of bomb shelters as proposed in the bill. Governor Frank J. Lausche of Ohio thought the shelters would be inadvisable, partly because they would take materials and manpower more urgently needed for other civil defense purposes. He proposed that this section of the bill be dropped but that the rest of the bill be expedited. He also thought there should be a cut-off date for the bill. So far, medical aspects of civil defense have not had a prominent part in the hearings.

NSRB Medical Handbook

The National Security Resources Board's medical handbook, delayed several months while agencies and organizations settled their differences over its contents, now is promised for December 28. The 280 pages are said by NSRB officials to present a description of civil defense medical aspects "as complete as we can make it." One important subject will be a treatment for burns, not a standard treatment but a treatment based on items to be included in regional medical stockpiles. Officials said no effort will be made to tell physicians what treatment to use, although the limitation on stockpile items inevitably will lead to a certain degree of standardization. It was emphasized, however, that the treatment presented will not "prejudice treatment of choice on the part of physicians, nor will it prejudice later treatment, possibly by another physician."

USPHS Grants

Meanwhile, the United States Public Health Service is promoting new research into treatment of extensive third degree burns by a $9,774 grant to Dr. Vernon E. Siler, University of Cincinnati. His project is described as a study of "clinical methods of removal of devitalized tissue from burned areas." Dr. Siler will do research on the removal of such tissue by application of organic compounds such as enzymes, without resort to surgery. Another USPHS grant, of $5,616, goes to Dr. Smith Freeman, Northwestern University Medical School, to support tests in the use of a new treatment, the "pthalazines," to stimulate renal function after bodily injury. In some cases of severe wounds, it has been noted that complete stoppage of renal function results. In all, 110 grants were made to 68 institutions in 32 states, at a total figure of $826,876. Some of the larger grants also had an indirect relation to national defense. The largest, for example, went to L. M. Fisher, American Public Health Association, Inc., New York, for research in sanitation administration, methods, programs, job evaluation and personnel requirements.

Precautions for Atomic Bomb Attacks

Another project under consideration by NSRB is the mass distribution of a pocket size card giving simple precautionary rules in the event of an atomic bomb attack. It is the outgrowth of a similar Defense Department card, which already has been issued to persons employed at the Pentagon. In place of the Defense Department card's instructions for reporting to duty stations and the like the NSRB leaflet would carry instructions regarding air raid warnings. The defense card carries such advice as "By the time the debris has stopped falling, there is no radiation hazard. . . . Report to receive treatment if necessary and to work to help over-all situation. . . . Keep your experiences to yourself and don't enlarge on what you hear from others. . . . Shock pressure from burst is not enough to kill; flying debris causes almost all injuries. . . . Burns on exposed skin occur up to two miles; light-colored clothes or any shielding material afford protection; keep your shirt on. . . . Fifty per cent of radiation occurs in the first second, 80 per cent in first 10 seconds, all in first 90 seconds. . . . If in the open, fall flat. . . . Stay put 10 seconds. . . . lingering radiation is so small it is not a hazard; disregard it."

The NSRB, which helped work out the Defense card, expects the one for the general population can be printed to sell for about 10 cents per hundred. Final decision to issue the cards has not been made, but the NSRB staff is completing its work.

Scientific Manpower

The appointment of Dr. Charles A. Thomas to head a Scientific Manpower Advisory Committee in the National Security Resources Board promises to solve one problem that had begun to cause complications. The committee will help NSRB Chairman W. Stuart Symington to evaluate scientific manpower proposals from government agencies, industry and scientific organizations. Further, says NSRB, the committee "will weigh the manpower requirements of a sound basic research program with requirements for applied research and development for production." Regarding medical manpower, Dr. Thomas' committee will assume jurisdiction of those groups in health and associated fields that do not technically fall within the province of Dr. Howard Rusk's Health Resources Committee, which also advises Chairman Symington. Between the two groups, responsibility will be divided for all scientific personnel, medical and nonmedical, according to present plans. This is expected to take in medical school staffs, research workers and technical personnel on hospital staffs.

National Science Foundation Board

The National Science Foundation Board meets January 3 to recommend a foundation director to President Truman. While the 24 members of the foundation board still have not received Senate confirmation, they met at the White House in mid-December to elect officers and members to the executive committee.

James B. Conant, president of Harvard University, was elected chairman of the board and Edwin B. Fred, president of the University of Wisconsin, vice chairman. The executive committee will select its own chairman. The committee has no power to act in the name of the board but will make recommendations to the board for its final approval. The law (P. L. 507, Eighty-First Congress) states that the board may "assign to the executive committee such of the powers and functions granted to the board . . . as it deems appropriate; except that the board may not assign to the executive committee the function of establishing policies, or the function of review and approval. . . ."

Members of the executive committee are Chester I. Barnard, president of Rockefeller Foundation; Detlev Bronk, president of Johns Hopkins University; Leo A. Dubridge, president of

California Institute of Technology; Paul M. Gross, dean of Duke University Graduate School; Dr. Robert F. Loeb, bard professor of medical services, College of Physicians and Surgeons, Columbia University; Joseph C. Morris, vice president of Tulane University; Elvin C. Stakman, chief of division of plant pathology and botany, University of Minnesota, and Conant and Fred.

Chemicals in Foods

The House Select Committee investigating the use of chemicals in food products concluded its hearings with a full week's testimony from food producers, public health officials and representatives of universities. One highlight of the week was the testimony of a physician, Dr. Robert A. Kehoe, director of the Kettering Laboratory, College of Medicine, University of Cincinnati. In blunt language, Dr. Kehoe told the committee that it was involved in a complicated problem, that there was need for regulation, but that if regulations were not reasonable and practical they would do more harm than good.

"The possible deleterious effects of the occurrence or incorporation of toxic, injurious or harmful substances into food materials and beverages used widely or generally in the United States," he said, "is a problem of such broad scope in the field of public health as to baffle the most enthusiastic and experienced investigator or guardian of the public safety." However, he thought that a "reasonable and fair solution" could be arrived at but that it could not be based on a prearranged program or formula for examining new products. He said that insistence on a thorough investigation of all new chemicals used in the food industry, regardless of the merit of such an investigation, "would flood all of the presently available experimental facilities of this type in the country with such investigative work at a time when for a number of reasons they are ill prepared for it and could hardly be spared for it." Regarding proposed new federal regulations, Dr. Kehoe cautioned the committee, "No useful purpose will be served, it is believed, by the setting up of legislative requirements that cannot be met, and indeed some considerable retrograde progress is likely to result from premature developments along this line."

He argued that modifications should be adopted with regard to all factors. "The powers and scope of action by the federal government might well be expanded in such manner as to apply greater and more uniform pressure on the food-producing and food-distributing industries of the country to meet their responsibilities to the community," he said.

When the committee chairman, Representative James J. Delaney (Democrat, New York), asked him for specific suggestions on regulations, Dr. Kehoe said, "The expansion of powers, . . . in the hands of any federal agency, should be done in such manner as not to impose an impossible burden of professional responsibility on any such agency or to invest it with arbitrary powers." However, he said, present regulations need "more teeth." He favored in general the technic used by the Food and Drug Administration in testing and certifying new drugs but proposed that a board or committee of outside experts of "broad experience" be called in to determine the degree of investigation that "could reasonably be done."

When asked whether he thought the primary responsibility should rest on the producers, he said he could not answer flatly yes or no. Dr. Kehoe said he believed the producers should have primary responsibility for supplying information but that the whole weight of investigation should not fall on the private organization "willing to deal with the problem." He said he favored some sort of a foundation to underwrite research of a protective nature.

Dr. Kehoe took issue with earlier technical witnesses who condemned the use of dichlorodiphenyltrichloroethane (DDT) in cow barns. He said the chemical in milk should be kept at the lowest possible level, "but I don't see how you are going to keep it out of cows' milk. It should be used with such care that contamination will be kept at a minimum."

Legislative Notes

The Senate Labor and Public Welfare Committee has reported out S. 4229, extending benefits of Public Law 16 (Seventy-Eighth Congress) to veterans of the Korean War. Public Law 16 grants vocational rehabilitation to disabled veterans. Companion bills have been introduced in the House by Congressman John Rankin (Democrat, Mississippi) and Olin Teague (Democrat, Texas). In letters to both House and Senate, President Truman has urged immediate passage of this legislation. . . . Senator Owen Brewster (Republican, Maine) has introduced a bill making the first Monday in February National Children's Dental Health Day, permanently setting aside that day for this purpose. Previously the proclamation was made each year. There are several similar bills in both Houses. . . . The December 12 *Congressional Record* carries the complete text of the *Collier's* magazine article, "Our Alarming Doctor Shortage," by Albert Q. Maisel. It was placed in the record by Congressman Abraham Multer (Democrat, New York). . . . S. 4246, introduced by Senator Elmer Thomas (Democrat, Oklahoma), would establish a Universal Civilian Defense Training Corps for high school students. Medical and other care would be provided for members attending summer camps. Physical and dental examinations would be given yearly by private physicians and dentists on a contract basis.

Poliomyelitis

The Public Health Service reports that the poliomyelitis death rate for the first eight months of 1950 is less than half that for the corresponding period last year. The estimated rate for the first eight months of 1949 was 1.3 per 100,000 of population, whereas a sampling this year shows a rate of 0.6 per 100,000 for the same months. The percentage of cases resulting in paralysis was approximately the same for both years. A large increase in cases for September and October, however, may bring mortality figures for both years more closely together, according to USPHS officials.

Notes

A Selective Service memo to local boards urges full cooperation with Red Cross on deferment for dependency. It also requests the boards to inform draft registrants of services supplied by Red Cross to men inducted. . . . Mortality statistics for 1949 show the death rate for females is decreasing more rapidly than the rate for males. The rate per thousand for males is 11.2 and for females 8.3. . . . Copies of "Priorities in Health Services for Children of School Age," a report of recent studies, is available from the Children's Bureau, Washington 25, D. C. . . . A change in regulations regarding Bureau of Indian Affairs' policy on treating non-Indian patients in Indian hospitals appears in the *Federal Register* of December 9. . . . Defense Secretary Marshall has called for wider industrial employment of the physically handicapped as essential to national defense. In a statement to the National Employ the Physically Handicapped Committee, he said their employment contributed to the military strength of the nation. . . . General Aniline and Film Corporation has begun production of a synthetic colloid used as a basis for a blood plasma substitute. It was used in Germany during World War II but has not been available in quantity in this country until now. The colloid, polyvinyl pyrrolidone, is a white powder, soluble in water and in many organic solvents. . . . 1,400 men, brought into Army reserves as a result of the doctor draft law, have been processed and have had their physical examination. All will be called to active duty shortly. . . . At this state of mobilization, any specific estimate of future medical needs for the armed forces would be little more than speculation. The important point is that, if the manpower buildup continues as now contemplated, hundreds of men who do not now expect to serve will be in uniform before the end of next year.

GOVERNMENT SERVICES

Public Health Service

Dr. Price Appointed an Assistant Surgeon General

Dr. David E. Price has been appointed an assistant surgeon general of the Public Health Service and an associate director of the National Institutes of Health. The appointment was made by Dr. Leonard A. Scheele, the Surgeon General. The position to which Dr. Price has been appointed was created because of the growth of the National Institutes of Health and particularly because of the increased administrative responsibilities entailed by the broadening of the grants programs, the inauguration of a large cortisone and pituitary adrenocorticotropic hormone (ACTH) research program and the initiation of new research in the metabolic and neurological diseases. Dr. Scheele said that Dr. Norman H. Topping, associate director of the National Institutes of Health for the past three years, will continue in that capacity and will assist the director, Dr. William H. Sebrell, with the intramural research program, including the representation of National Institutes of Health interests with other governmental agencies.

As associate director, Dr. Price will assist the director in representing the Public Health Service's National Institutes of Health in extramural operations, including coordination of the various grants programs, community services and relations with the various voluntary organizations with which the Institutes share mutual interests.

During his administration as chief of the Division of Research Grants from 1948 to the present, the allocation of grants-in-aid for medical research to nonfederal institutions has increased from about $10,000,000 to $35,000,000 yearly. Dr. Scheele said that Dr. Price has administered this program with great effectiveness. He has maintained a major principle on which the grants program was founded—freedom of research for the individual investigator.

Dr. Price has a B.A. from the University of California, an M.D. from the University of California School of Medicine and Dr. P.H. from the Johns Hopkins School of Hygiene and Public Health. He is a diplomate of the American Board of Preventive Medicine and Public Health.

Decrease in Female Death Rate

The death rate for females is decreasing more rapidly than the rate for males according to estimates of 1949 mortality statistics compiled by the National Office of Vital Statistics. Between 1940 and 1949, the death rate for the female population decreased 13 per cent while the rate for males decreased 7 per cent. While the death rate for every age group has been declining since 1940, the rate for children 1 to 14 years decreased 40 per cent, and in the age group 65 to 74 years the decrease was only 10 per cent.

The death rate for males is higher than for females in each of the age groups. The largest relative difference between the rates for males and females in 1949 was in the age group 15 to 24 years, in which group the rate for males exceeded the rate for females by 89 per cent. The percentage differences between the death rates for males and females in the other age groups over infancy have also increased but not as rapidly.

Greek Physicians in Training in Anesthesia

Two Greek physicians arrived in the United States on November 19 for one year of advanced training under programs supervised by the Division of International Health of the Public Health Service. Both physicians were sent here for special training in anesthesia They were selected by a committee of physicians working through the Greek Ministry of Hygiene. Dr. Evangeles Anagnostopoulos will go to Hartford Hospital, Hartford, Conn., where he will study under the direction of Dr. Ralph Tovell, director of anesthesia. Dr. Anagnostopoulos is the pathologist and assistant to the professor of surgery at the University Medical School, Salonica. Dr. Anastassios Karasoulos will report at the University of Minnesota Hospital for training under the direction of Dr. Ralph T. Knight, director of the division of anesthesiology. Dr. Karasoulos has been the consultant for the Prenatal Clinics of the Patriotic Foundation of Social Welfare and Assistance, a semiofficial agency for maternal and child hygiene.

Swineherd's Disease Due to Leptospira Pomona

The following report was released by the U. S. Public Health Service, November 23:

"The Regional Laboratory at Montgomery, Alabama (Virus and Rickettsia Section, Communicable Disease Center, Public Health Service), reports marked rises in serum agglutination titers for Leptospira pomona in 'nearly all' of 22 individuals tested. These were from a group of 50 young adults and adolescents in southern Alabama who developed signs and symptoms suggestive of aseptic meningitis. They had all bathed in an artificial swimming area of a slow moving creek on July 4, 1950. Serological tests for common central nervous system infections and for Leptospira icterohemorrhagia and L. canicola did not indicate recent infection. This is the first report in the United States of swineherd's disease due to this species of Leptospira."

Miscellaneous

Navy Reserve Officers on Duty with Army

Secretary of the Army Frank Pace Jr. has reported to the Secretary of Defense, General Marshall, that the 570 Navy reserve medical officers recently called to active duty and detailed to the Army have reported for Army duty and that "the project has been a complete success." In a memorandum to Secretary Pace and to Secretary of the Navy Francis P. Matthews, General Marshall said that he was pleased with the manner in which this processing of medical officers was accomplished at the Medical Center and that he appreciated this evidence of close and effective cooperation between the two services.

The reserve medical officers, part of the group who received their medical training under the Navy's wartime V-12 Program, were ordered to active duty for Army assignments between Oct. 15 and Nov. 6, 1950, on instructions from the Secretary of Defense. The action was taken in accordance with instructions of the President and conforms to the Department of Defense priority system for recall of medical and dental reserve officers, announced Sept. 7, 1950, for more efficient utilization of these reserve officers. Allocations of reserve medical officers, approved by Dr. Richard L. Meiling, Director of Medical Services, are made available from priority group I for duty according to the current needs of the three military services.

Committee Membership Changes

Dr. I. S. Ravdin, Philadelphia; Dr. William S. McCann, Rochester, N. Y., and Dr. Francis C. McLean, Chicago, have been appointed to the Committee on Medical Sciences of the Department of Defense Research and Development Board. These new members were on active duty with the armed forces duri World War II.

MEDICAL NEWS

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARKANSAS

Appoint Professor of Otolaryngology.—Dr. Frank S. Forman Jr., Kansas City, has been appointed professor of otolaryngology at the University of Arkansas Medical School, Little Rock, effective in January. He will do research as well as teaching and will serve in the Veterans Administration Hospital at Little Rock. Since 1946 Dr. Forman has practiced in Kansas City.

CALIFORNIA

Hospital for Imperial Valley.—Pioneers Memorial Hospital was opened recently near Brawley, at the center of valley population and the convergence of roads. The hospital will serve 65,000 persons and may be reached in a short time from any point in El Centro and Calipatria. It will eliminate trips of 125 miles to San Diego and longer ones to other California cities. The hospital has 88 beds in private and semiprivate room facilities. The central building and technical facilities are designed so that eventual growth to 200 beds can be attained.

Forty-One Doctors Achieve Emeritus Standing.—Forty-one physicians on the staff of Los Angeles County Hospital were feted at a dinner November 15. All had attained the age of 65 years and received their diplomas of service and emeritus standing on the attending staff. During the evening of reminiscence the history of the hospital was presented by two of the physicians, who traced its growth from a little adobe building on Eternity Street operated by the Sisters of Charity in 1858 to the 3,600 bed institution it is today. It has 350 house physicians and attending staff of 1,000 physicians and surgeons for its average patient load of 3,000. Those who were retired are Drs. Irving R. Bancroft, John V. Barrow, Tobias I. Birnberg, Andrew Bonthius, Charles W. Bonynge, William A. Boyce, J. Mackenzie Brown, Halbert W. Chappel, William A. Clark, Benton N. Colver, Roland S. Cummings, Guy B. Desparois, Frank S. Dolley, John Dunlop, Paul A. Ferrier, Alfred E. Galant, Ernest M. Hall, Edward W. Hayes, Albert L. Hill, Carl R. Howson, William W. Hutchinson, Samuel D. Ingham, A. Ray Irvine, Madison J. Keeney, J. Mark Lacey, August H. Larson, George P. Laton, Edmond M. Lazard, James C. Negley, John W. Nevius, Gilbert R. Owen, Francis M. Pottenger, Hans E. Schiffbauer, Solomon Strouse, Charles T. Sturgeon, Raymond G. Taylor, Roy E. Thomas, Gilbert J. Thomas, Leslie E. Trott, Walter F. Wessels and Percival M. Williams.

CONNECTICUT

Dr. Howard Appointed Chairman of Council.—Dr. Joseph H. Howard, Bridgeport, has been chosen chairman of the Governing Council of the Connecticut State Medical Society succeeding Dr. Thomas P. Murdock of Meriden, who resigned to carry on new duties as a member of the American Medical Association's Board of Trustees. Dr. Howard is vice president of the Council of New England State Medical Societies and of the Connecticut Medical Service, and president of the Connecticut Cancer Society. In 1945 he was president of the State Medical Society. He is director of the department of obstetrics at St. Vincent's Hospital, Bridgeport, and a member of the staff at Bridgeport Hospital.

ILLINOIS

State Tuberculosis Hospital to Open.—The 100 bed Mount Vernon State Tuberculosis Sanitarium, the first state institution of its kind in Illinois, is nearing completion and is expected to open early next year. It will be operated by the State Department of Public Health. Dr. Isadore Zapolsky of Elgin, who has been appointed medical superintendent, was a staff physician at the Chicago Tuberculosis Sanitarium for many years, served as medical officer in the U. S. Army for two and a half years and has been in charge of the tuberculosis unit of the Elgin State Hospital since March 1948.

One Million Chest Roentgenograms.—The Illinois Department of Public Health has taken the one millionth chest roentgenogram in its five year old tuberculosis case-finding program. The first mobile x-ray unit began operating on Jan. 10, 1945. Today five x-ray busses and one transportable unit are in operation. The state health department works closely with local groups who sponsor the surveys, i. e., county or city health departments, county tuberculosis associations and sanatorium boards. After the roentgenograms have been processed by the Illinois Department of Public Health, they are sent to the local sanatorium or health department, where they are kept as a permanent record.

Chicago

Presbyterian Hospital School of Nursing.—Presbyterian Hospital laid the cornerstone of its 15 story $2,800,000 school of nursing November 29. When completed next summer it will house 300 students and provide administrative offices, class rooms and laboratories. The new building replaces the Sprague home on Congress Street which is being torn down to make way for the Congress Street superhighway.

Grant for Study of Human Energy.—Northwestern University has received a grant of $4,500 from the Rockefeller Foundation, New York, for study of the creation of energy in the human body. Dr. Irving M. Klotz, professor of chemistry and biology and a member of the faculty since 1942, will direct the research. University scientists will investigate the processes by which chemical fluids in the human body combine with food particles to produce energy.

Dr. Rattner to Head Dermatology Department.—Dr. Herbert Rattner, professor of dermatology, Northwestern University Medical School, has been appointed chairman of the department succeeding Dr. Edward A. Oliver, now professor emeritus of dermatology. Dr. Rattner served as a staff dermatologist in the Cook County, Michael Reese, Augustana and South Shore hospitals before joining the medical school.

University Downtown Lectures.—A series of lectures on biologic aggression and biochemical defenses will be presented in the winter schedule of the University of Chicago's downtown center at 19 South La Salle Street. Frank W. Putnam, Ph.D., assistant professor of biochemistry, will open the series at 8:00 p. m. January 10, when he speaks on "Bacterial Toxins and Biologic Warfare." Other lecturers will be:

Jan. 17, James W. Moulder, Ph.D., assistant professor of biochemistry, Antibodies.
Jan. 24, Bernard S. Schweigert, Ph.D., assistant professor of biochemistry, The Principles of Biological Antagonism.
Jan. 31, James W. Moulder, Ph.D., Chemical Warfare Among Microorganisms.
Feb. 7, Bernard S. Schweigert, The Attack on Anemias.
Feb. 14, Albert Dorfman, assistant professor of pediatrics, Biochemistry of Connective Tissue.
Feb. 21, Albert Dorfman, ACTH, Cortisone and Rheumatic Diseases.
Feb. 28, Thomas B. Coolidge, associate professor of biochemistry, Biochemical Approaches to Dental Health.
March 7, Thomas B. Coolidge, Biological Defenses Against Acids and Bases.
March 14, Elwood B. Jensen, assistant professor of chemistry, The Biochemist and the Cancer Problem.

Prerequisite for the lecture series, which may be attended for college credit, is university work in chemistry, biology or physics. The series ticket is $18, single admission is $2.

In another winter series of the university advances in the fight against death and disease will be reported. Dr. William J. Dieckmann, chairman, department of obstetrics and gynecology, will open the series with a discussion on "Safe Childbirth." He will speak at 5:30 p. m. on January 9 at 19 South La Salle Street. Other lecturers will be:

Jan. 16, Thomas W. Lester Jr., assistant professor of medicine, Controlling Airborne Infections.
Jan. 30, Dwight E. Clark, associate professor of surgery and secretary *of the department*, Radioactive Iodine: New Treatment for Thyroid Diseases.
Feb. 6, M. Edward Davis, professor of obstetrics and gynecology, Diagnosis and Treatment of Gynecologic Cancer, Sterility and Menopause.
Feb. 13, Leon O. Jacobson, associate professor of medicine, The Fight Against Cancer.

Series tickets are $3.60 each and single admission, $1.

KANSAS

Narcotic Violation.—Dr. Hugh A. Hope, Hunter, pleaded guilty on four counts of an indictment charging violation of the federal narcotic laws in the U. S. District Court at Topeka and on October 13 was sentenced on one count to serve a term of one year and one day, was fined $3,000 on another count and sentence was suspended on the two remaining counts. He was placed on probation for a period of three years. Execution of the sentence was suspended until December 1.

MARYLAND

Clinics for Epileptic Children.—A statewide program of assistance to epileptic children was recently begun under a special grant to the Maryland Health Department by the Children's Bureau of the Federal Security Agency. The demonstration program will be based on recent advances in the control of epilepsy. The Johns Hopkins School of Medicine and the University of Maryland School of Medicine and College of Physicians and Surgeons will cooperate in the program. The medical schools will furnish specialists to help in the operation of two diagnostic clinics in Baltimore, to which children throughout the state will be referred. All the county health departments expect to take an active part by referring children to the clinics, supplying necessary drugs and working closely with the local physicians in carrying out the treatment recommended in each case.

MISSOURI

Rehabilitation Center in St. Louis.—Washington University's plans for a rehabilitation center at the School of Medicine in St. Louis were given impetus this month when Mrs. Oscar Johnson, widow of the late shoe manufacturer, pledged 6,000 shares of the capital stock of the International Shoe Company to be applied to the project. Present value of the stock is $240,000. The sum is to be used with other gifts to construct a building that will house the occupational therapy and physical therapy research laboratories. Provision is made that, if by Jan. 1, 1956, sufficient supplementary funds shall not have been raised, proceeds of Mrs. Johnson's gift will be used for support, maintenance and development of the Oscar Johnson Institute, a hospital in the medical center for research in otolaryngology and ophthalmology. Plans for the center were drawn up after consultation with Dr. Howard Rusk, former member of the Washington University medical faculty, now at New York University-Bellevue Medical Center in New York.

MONTANA

State Secretary Goes Into Air Force.—The Executive Committee of the Montana State Medical Association has appointed Dr. Everett H. Lindstrom of Helena to succeed Dr. Herbert T. Caraway, Billings, as secretary-treasurer. Dr. Caraway was recently commissioned a major in the Medical Corps Reserve of the Air Force and is awaiting orders to report for active duty.

NEW JERSEY

Society News.—The New Jersey Orthopedic Society at the recent annual meeting elected Dr. Nicholas S. Ransohoff, Asbury Park, president; Dr. Raphael R. Goldenberg, Paterson, president-elect; Dr. Philip Willner, Newark, secretary, and Dr. Roy R. Ciccone, Passaic, treasurer.

Regional Conference on Civil Defense.—The governor of New Jersey has invited the governors of Delaware, New York, Massachusetts and Pennsylvania to invite representative teams to a four state regional conference on local health services and civil defense January 22-23 at the Nassau Tavern in Princeton. The National Health Council, through its National Advisory Committee on Local Health Units, is serving in an advisory capacity to the organizing committee.

NEW YORK

State Cancer Clinic Directory.—The Bureau of Cancer Control of the State Department of Health has prepared a directory of cancer detection centers and tumor clinics, which lists county, city, hospital and date and time of clinics throughout the state. It suggests that patients be referred through the family physician or, where this is not possible, that the clinic admitting officer be consulted concerning the proper procedure. Fee schedules vary, but no patient will be refused admission because of inability to pay, the directory states. The directory was prepared with the cooperation of city, county and district health officers, who submitted information regarding clinics in their specific areas. The directory is available to physicians, nurses and others concerned with clinic procedures.

New York City

Plea to Reserve Television Channels for Education.—The Council of the New York Academy of Medicine has endorsed the appeal to the Federal Communications Commission for setting aside at least 20 per cent of the channels available on television for educational purposes. The academy points out that, with the growth of the commercial programs, less and less time has been given to health organizations, despite the fact that radio channels are of "public domain" and are released to the stations on a privileged rather than on a proprietary basis. The reservation of a definite percentage of the available television channels for educational purposes should prevent the similar choking off of educational services on television, the academy said.

Course in Allergy.—A short course to cover four sessions on the nature and cause of allergy and its practical management will be conducted in the New School for Social Research beginning January 23 by Dr. Arthur F. Coca. Dr. Coca is honorary president of the American Association of Immunologists. He was the founder and for many years the editor of the *Journal of Immunology* and is the author of a textbook on allergy. Dr. Coca plans to encourage students to experiment throughout the course with the technic of using the pulse to determine causes of allergy symptoms.

Dr. Cherkasky to Direct Montefiore Hospital.—Dr. Martin Cherkasky, Hartsdale, N. Y., has been named director of the Montefiore Hospital to succeed Dr. Ephraim M. Bluestone, director since 1928. Dr. Bluestone was appointed consultant to the hospital, including its Montefiore Hospital Country Sanatorium at Bedford Hills. Both appointments are effective January 1. Dr. Cherkasky has been serving as full time chief of the hospital's division of social medicine. He is also physician-in-charge of the Family Health Maintenance Demonstration, recently inaugurated at the hospital.

Dr. Bluestone this month completes 30 years of service as an executive in the field of organized medical care. He served as assistant director of the Mount Sinai Hospital from 1920 to 1926 and as director of the Hadassah Medical Organization for all Palestine from 1926 to 1928. Dr. Bluestone is a member of the faculty of the Columbia University School of Hospital Administration.

Academy Requests Abstracts of Clinical Research Papers.—The Committee of Medical Education of the New York Academy of Medicine invites all research workers of Greater New York and cities within 100 miles to submit abstracts of papers for presentation at the Clinical Research Meeting to be held April 4-5, when investigators may present results of clinical research. The presentations will be confined to original research in clinical medicine or surgery, or to research applicable to medicine or surgery in all clinical branches. Preference will be given to papers that have not been presented before a society (other than intramural). Investigators are requested to state whether this work has been published or has been submitted for publication; also, in cases in which the investigator is working under the head of the department of a hospital or research institute, approval of the head of department must accompany the application. The presentation in quadruplicate, not to exceed 500 words in length, should be sent to the Secretary of the Committee of Medical Education, New York Academy of Medicine, 2 East 103d Street, New York 29, not later than February 1. A formal invitation to participate in the program will be extended by the committee to the authors of papers selected.

OHIO

Hospital News.—Ground was broken in November for the new Youngstown Receiving Hospital, which is to be built at a cost of about $1,000,000. This will be the ninth receiving hospital in Ohio.

Museum Models on Reproduction Available.—Bruno Gebhard, director, Cleveland Health Museum, announced December 6 that the museum will carry on the work of Dr. Robert Latou Dickinson, originator and designer of the world famous "Birth Series" models for lay and professional education. Since 1945 the Cleveland Health Museum has held exclusive duplication rights on these life-size, three dimensional models of human reproduction. Duplicates are available. Illustrated folders will be sent on request.

SOUTH CAROLINA

State Orthopedic Association.—The South Carolina Orthopedic Association was organized at a meeting November 8 in Columbia. Members of the association will be active fellows, engaged in practice of orthopedic surgery exclusively, and junior fellows, physicians who are in training for practice in orthopedic surgery. After the organizational meeting Dr. Peter B. Wright, professor of orthopedic surgery at the University of Georgia School of Medicine, Augusta, spoke on the basic principles of the specialty. Officers elected are Dr. William A. Boyd, Columbia, president; Dr. Austin T. Moore, Columbia, vice president, and Dr. George R. Dawson Jr., Florence, secretary-treasurer. Elected to the executive committee were officers of the association and Dr. Frank H. Stelling, Greenville, and Dr. Frank A. Hoshall, Charleston.

UTAH

Cancer Research Building.—A four story, $413,000 cancer research building is scheduled to open in December as a part of the proposed University of Utah Medical Center in Salt Lake City. The basement of the structure will be used for tracer studies with radioisotopes. The first floor will be occupied by offices, a library and seminar rooms, the second floor will be devoted to biochemical research, the third floor to studies of the physiology of cancer and the fourth to biologic research. Special rooms will include a tissue culture laboratory, dark rooms, optical laboratories and rooms for housing experimental mice.

WEST VIRGINIA

Society News.—Dr. Raphael J. Condry, Elkins, was named president of the West Virginia Heart Association at the annual meeting in Huntington, October 26-27. Dr. James L. Wade of Parkersburg was named vice president; Dr. John S. Pearson of Huntington, secretary, and Mr. R. E. Plott of Charleston, treasurer

Establishing a Four Year Medical School.—The house of delegates of the West Virginia State Medical Association at a special meeting in Clarksburg November 19 went on record unanimously in favor of establishing a four year school of medicine and dentistry as a part of West Virginia University. Resolution urging the creation of the school had previously been adopted at regular sessions of the house of delegates in August 1949 and July 1950. It was the first called meeting of the delegates in recent years and was one of the most largely attended meetings ever held by the association. A copy of the resolutions adopted by the Board of Governors of the West Virginia University October 27 was read. The board recommended the "immediate expansion of the university's present two year medical school into a four year medical and dental school, teaching hospital, nurses training school and state health center on the campus of the university at Morgantown." The study on which this recommendation is based shows that the required capital expenditures for this program would total from $750,000 to $1,000,000.

The discussion at the meeting also included the reports filed by Dr. Herman G. Weiskotten, dean of Syracuse (N. Y.) University College of Medicine, and Dr. Wilburt C. Davison of Durham, N. C., dean of Duke University School of Medicine, who made surveys concerning the need for such a school and both of whom advocated the immediate construction of a four year school. The next regular session of the legislature will convene at Charleston January 10, and if the usual procedure is followed, the report of the Interim Committee will be submitted to the governor and the legislature early in the session.

WISCONSIN

Course on Cortisone and ACTH at Madison.—The University of Wisconsin Medical School will present January 17 an intensive one day course on cortisone and pituitary adrenocorticotropic hormone (ACTH), designed to appeal to physicians in practice. The course will be supervised by Dr. Edgar S. Gordon, associate professor of medicine, with Dr. Seymour B. Crepea, assistant professor of medicine, and Roland K. Meyer, Ph.D., professor of zoology, assisting. Two medical films will be presented through the courtesy of Armour Laboratories, Chicago. The fee is $3. Further inquiry should be directed to Dr. Robert C. Parkin, 418 North Randall Avenue, Madison 6.

GENERAL

American Academy of Forensic Sciences.—This organization will hold its third annual meeting March 1-3 at the Drake Hotel, Chicago. All persons desiring to present papers are requested to contact Dr. Abraham W. Freireich, chairman of the program committee, 180 Hempstead Avenue, Malverne, N. Y. Additional information may be obtained from the office of the president, Dr. R. B. H. Gradwohl, 3514 Lucas Avenue, St. Louis 3.

Course in Orthoptics.—The American Orthoptic Council will present its fourth annual intensive course in orthoptics in Boston, July 5-Aug. 31, 1951. Tuition is $150. The council will make an effort to see that all students enrolled have places to complete their practical training following the course. Applicants must be at least 18 years of age, have had a high school education and be sponsored by an ophthalmologist. A few scholarships are available from the Delta Gamma Fraternity Project. Inquiries should be addressed to the American Orthoptic Council, Dr. Richard G. Scobee, 40 S. Kingshighway, St. Louis 10.

Masons Finance Research on Dementia Precox.—The Supreme Council, Thirty-Third Degree, of the Ancient Accepted Scottish Rite of Freemasonry for the Northern Jurisdiction, comprising the states north of the Ohio River and east of the Mississippi River, has appropriated $1,000,000 to endow a benevolent foundation, the endowment fund to be increased from time to time. A sum of $50,000 was appropriated for further research into dementia precox. The Supreme Council began its program of study on demential precox 18 years ago and has expended $900,000 in the work up to the present time. Dr. Richard A. Kern of Philadelphia is chairman of the council's Committee on Benevolences.

Society Elections.—Newly elected officers of the New England Obstetrical and Gynecological Society are Dr. Arthur T. Hertig, Winchester, Mass., president; Dr. Joseph H. Howard, Bridgeport, Conn., vice president; Dr. Frederick L. Good, Boston, treasurer, and Dr. Carmi R. Alden, Boston, secretary.—New officers of the Western Surgical Association elected at the meeting in Minneapolis December 1 include Dr. Erwin R. Schmidt, Madison, Wis., president; Dr. Michael L. Mason, Chicago, secretary, and Dr. Herbert H. Davis, Omaha, treasurer. The next annual meeting will be held in Colorado Springs at the Broadmoor Hotel Nov. 29-Dec. 1, 1951.

Dr. Kern to Head Editorial Board.—Starting with the January issue, the *American Journal of the Medical Sciences* will be under the editorial direction of Dr. Richard A. Kern, professor and head of the department of medicine, Temple University School of Medicine, Philadelphia. With Dr. Kern will be a new associate editor, Dr. Thomas M. Durant, professor of clinical medicine at Temple, and a new assistant editor, Dr. Chris J. D. Zarafontis, associate professor of internal medicine at Temple. These men will succeed the former editorial board headed by Dr. Edward B. Krumbhaar of the University of Pennsylvania, Philadelphia. Dr. Krumbhaar retired after 25 years' association with the journal.

Reports on Epidemics.—Dr. Archie L. Gray, Mississippi State Board of Health, has reported to the U. S. Public Health Service an outbreak of acute gastroenteritis in a city with a population of 40,000. There were 18 cases with onset of illness between September 16 and 25. Investigation revealed that a cream-filled pastry was the vehicle of transmission.

Dr. W. R. Geidt, Washington State Department of Health, has reported an outbreak of 13 cases of trichinosis in Seattle. The vehicle of infection was thought to be sausage made late in October from hogs shipped from the West North Central states. The onset of infection was early in November. Diagnosis was confirmed clinically and by muscle biopsy in one case. The routine processing of meat was considered to be satisfactory.

Dr. Williams Wins Chemistry Award.—Professor Roger J. Williams, Sc.D., of the University of Texas, widely known for work in the field of vitamins, was chosen the 1950 winner of the Southwest Award of the American Chemical Society at the society's annual Southwest regional meeting. Professor Williams has been director of the University of Texas Biochemical Institute since 1940. The award, a bronze plaque and $200 in cash, was presented to him at a luncheon in San Antonio, December 9. He came to the University of Texas in 1939. He has been consulting biochemist at the M. D. Anderson Hospital for Cancer Research, Houston, since 1942. He serves on the Food and Nutrition Board of the National Research Council and was formerly with the U. S. Public Health Service. He has received the Mead Johnson Award of the American Institute of Nutrition and the Chandler Medal of Columbia University, which he shared in 1942 with his brother, Robert R. Williams, Sc.D., New York.

Meeting of International College of Surgeons.—The Southern Section of the International College of Surgeons will meet at the Biltmore Hotel, Atlanta, Ga., January 11-13. The program lists the following lecturers and their subjects:

Amos R. Koontz, Baltimore, Tantalum Mesh in Hernia Repair.
Karl Meyer, Chicago, Trends in Treatment of Carcinoma of the Left Colon.
Merrill N. Foote, Brooklyn, N. Y., Nodular Goiter.
Harry Bacon, Philadelphia, Postoperative Abdominal Wound Dehiscence.
Raymond McNealey, Chicago, Ulcerative Colitis.
Arnold S. Jackson, Madison, Wis., Surgical Lesions of the Neck.
Philip Thorek, Chicago, Trends in Esophageal Surgery.

Other speakers include Drs. Herbert Acuff, Knoxville; Richard Cattell, Boston; Gilbert F. Douglas Jr., Birmingham, Ala.; Lawrence S. Fallis, Detroit; William G. Hamm and Exum Walker, Atlanta, Ga.; De Lou P. Hall, Louisville, Ky.; Claude J. Hunt, Kansas City; Frank Meleney, New York, and Howard D. Trimpi, Philadelphia.

Damon Runyon Clinical Research Fellowships—The Committee on Growth of the National Research Council, acting for the American Cancer Society, is accepting applications for Damon Runyon Senior Clinical Research Fellowships These fellowships in cancer research are financed by a grant of $110,000 from the Damon Runyon Memorial Fund to the American Cancer Society Applications should be filed before March 1, 1951, on behalf of the applicant by the institution where the fellow will be in residence Applications will be considered in April and fellowships ordinarily will begin July 1, though this date may be varied at the request of the fellow Awards are made directly to the institution on an annual basis and renewal may be requested Persons now holding these fellowships will be notified regarding applications for renewal Communications should be addressed to the Executive Secretary, Committee on Growth, National Research Council, 2101 Constitution Avenue, N W, Washington 25, D C.

FOREIGN

Poisonous Smog Kills 15 in Mexico—A poisonous refinery smog which spread over the suburb of Poza Rica, an eastern Mexico oil town, took the lives of 15 persons November 24, according to the Associated Press Forty of the 60 persons affected were hospitalized, and three were in serious condition the following day It is believed that the smoke from a refinery plant mixed with a heavy fog was blown down on the settlement Poza Rica is surrounded by oil and gas wells in the low hills, and the afflicted settlement, which bears no name of its own, is among these hills

DEATHS

Palmer, Walter Walker ⊕ New York; born in Southfield, Mass., Feb. 27, 1882; Harvard Medical School, Boston, 1910; served an internship at the Massachusetts General Hospital in Boston, where he accepted the Henry P. Walcott Fellowship and where from 1913 to 1915 he served as resident physician; was an instructor in physiological chemistry at Harvard; in 1915 moved to the Rockefeller Institute in New York, serving as an assistant in medicine and assistant resident physician; in 1917 became associate professor of medicine at Columbia University College of Physicians and Surgeons; during World War I served as first lieutenant in the medical reserve corps of the U. S. Army; in 1919 accepted the full time position of associate professor of medicine at Johns Hopkins University and was made an associate visiting physician to the Johns Hopkins Hospital, where he remained until 1921; later returned to New York, becoming Bard professor of medicine at Columbia and director of the medical service at the Presbyterian Hospital, serving in this capacity until 1947, when he became emeritus professor at the school and consultant in medicine at the hospital; since 1947 director of the Public Health Research Institute of New York; past president of the Harvey Society and the American College of Physicians, of which he had been a vice president, governor and regent; member of many professional societies, including the Association of American Physicians, the American Society for Clinical Investigation, the Society for Experimental Biology and Medicine and the New York Academy of Medicine; member of the National Board of Medical Examiners from 1921 to 1943; during World War II served as chairman of the Committee on Drugs and Medical Supplies of the National Research Council and was a member of its committee on medicine; an advisor to the War Production Board and a member of the advisory committee of the Office of Scientific Research and Development; in 1945 and 1946 was chairman of the medical advisory committee appointed by Vannevar Bush to prepare a report for the President on the establishment of a National Science Foundation; in 1919 appointed to the Council on Pharmacy and Chemistry of the American Medical Association, in which he served as vice chairman from 1936 until his retirement in 1947; recipient of the honorary degree of Doctor of Science from Amherst College in 1922, from Columbia in 1929 and Princeton in 1947; his early collaboration with Prof. L. J. Henderson culminated in the classical studies on acid-base equilibrium; made significant contributions to knowledge of diabetes, thyroid physiology and the management of thyroid disease; author of numerous articles and at one time was a member of the editorial board of *Medicine* and also of the *Archives of Internal Medicine;* at the time of his death was editor in chief of the Nelson Loose-Leaf Medicine and chairman of the advisory committee of the *American Journal of Medicine;* died suddenly on his farm at Tyringham, Mass., October 28, aged 68, of coronary disease.

Nuttall, John Price, Santa Monica, Calif.; born in Port Royal, Ky., Jan. 30, 1878; Hospital College of Medicine, Louisville, Ky., 1902; member of the American Medical Association and in 1938 and 1939 a member of its House of Delegates; past president of the American Association of Medical Milk Commissions; past president and vice president of the Los Angeles County Medical Society; formerly secretary of the Henry County (Ky.) Medical Society and health officer of Henry County; served on the staff of the Battle Mountain Sanatorium in Hot Springs, S. D.; during World War II was a member of the Committee on Procurement and Assignment of Los Angeles County; emeritus chief of staff at Santa Monica Hospital; died in the Veterans Administration Hospital in West Los Angeles October 7, aged 72, of arteriosclerosis.

Milnor, Guy Champion ⊕ Honolulu, Hawaii; born in Warrensville, Pa., Jan. 31, 1887; University of Pennsylvania School of Medicine, Philadelphia, 1914; past president of the Hawaii Territorial Medical Association and Honolulu County Medical Society; formerly secretary of the Hawaiian Territorial Board of Medical Examiners and for many years member of the board of health; served during World War I; member of the selective service appeal board; fellow of the American College of Surgeons; consulting obstetrician and gynecologist, Kapiolani Maternity and Gynecological Hospital, where he was a member of the board; senior member of the clinic; consultant and gynecological surgeon, St. Francis Hospital and the Queen's Hospital, where he died October 26, aged 63, of cerebral hemorrhage.

Doughty, Roger Gamble, Columbia, S. C.; born in Augusta, Ga., in 1895; Johns Hopkins University School of Medicine, Baltimore, 1920; past president of the Columbia Medical Society and past vice president of the Southern Surgical Association; president of the South Carolina Surgical Society; member of the American Medical Association, Eastern Surgical Society and the Southeastern Surgical Congress; fellow of the American College of Surgeons; member of the founders group of the American Board of Surgery; affiliated with Columbia Hospital, where he was a member of the board of trustees, and Veterans Administration Hospital; consulting surgeon, South Carolina State Hospital and Camden (S. C.) Hospital; died October 19, aged 55, of coronary occlusion.

Carr, Alexander Moncrieff, Lewisburg, W. Va.; born in Edinburgh, Scotland, Oct. 1, 1889; University of Pennsylvania School of Medicine, Philadelphia, 1918; member of the American Association of Industrial Physicians and Surgeons; formerly assistant professor of preventive medicine and public health at Detroit College of Medicine and Surgery, now Wayne University College of Medicine in Detroit; while located at Madison, Wis., was connected with the U. S. Public Health Service and was health officer of that city; formerly health officer of Bradley County, Tenn.; health officer for district number two, which includes Monroe, Pocahontas and Greenbrier counties; died suddenly in Charleston November 13, aged 61, of coronary occlusion.

Carter, William Wesley, Bronxville, N. Y.; born in Wilmington, N. C., Nov. 23, 1869; University of the City of New York Medical Department, New York, 1895; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; consulting otolaryngologist, South Side Hospital, Bayshore, Bellevue Hospital and Gouverneur Hospital, New York; rhinoplastic surgeon, Elizabeth (N. J.) General Hospital; died in St. Simons Island, Ga., October 11, aged 80, of heart disease.

Toumey, James William ⊕ Boston; Columbia University College of Physicians and Surgeons, New York, 1926; specialist certified by the American Board of Orthopaedic Surgery; member of the American Orthopaedic Association and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served overseas in the U. S. Naval Reserve during World War II; consultant in orthopedic surgery, U. S. Naval Hospital, Chelsea; affiliated with the Lahey Clinic, New England Deaconess Hospital and the New England Baptist Hospital, where he died October 18, aged 50, of carcinoma of the liver.

Meyer, Monte Fiore ⊕ New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1914; clinical assistant professor of otolaryngology at Louisiana State University School of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Oto-Laryngology; formerly secretary of the New Orleans Ophthalmological and Otolaryngological Society; served during World War I; member of the staff of Hotel Dieu, Charity Hospital and Eye, Ear, Nose and Throat Hospital; died October 3, aged 56, of coronary occlusion.

Walker, Thomas Franklin ⊕ Great Falls, Mont.: born in Kokomo, Colo., in 1890; University of Colorado School of Medicine, Denver, 1912; specialist certified by the American Board of Pathology; fellow of the American College of Physicians; member of the American Society of Clinical Pathologists; served as secretary-treasurer of the Medical Association of Montana; past president of the Cascade County Medical Society; formerly county health officer; on the staff of Columbus Hospital, where he died October 22, aged 60, of carcinoma of the right lung.

Doran, William Guy ⊕ New York; born in New York Oct. 14, 1885; Cornell University Medical College New York, 1911; formerly associated with the U. S. Public Health Service; served during World War I; member of the American Academy of Orthopaedic Surgeons; fellow of the International College of Surgeons and the American College of Surgeons,

---

⊕ Indicates Fellow of the American Medical Association.

affiliated with the Medical Center, Jersey City, and St. Mary's Hospital, Hoboken, N. J.; on the staff of St. Vincent's Hospital; died in South Orange, N. J., November 1, aged 64, of carcinoma of the stomach.

Lynam, Frank, Minneapolis; Harvard Medical School, Boston, 1893; affiliated with the Barnes Duluth Shipbuilding Company during World Wars I and II; in 1922 administrator of the American Relief Administration in Russia; part time instructor in surgery, 1928-1929, surgeon in health service from 1929 to 1935 and instructor in first aid during the same period at the University of Michigan Medical School in Ann Arbor; at one time medical supervisor for the British government in the Bahamas; died October 8, aged 84, of cancer of the pelvic bone.

Adles, Max, Normandy, Mo.; Missouri Medical College, St. Louis, 1898; member of the American Medical Association and the Illinois State Medical Society; formerly practiced in DuQuoin, Ill., where he had been a member of the board of health; died October 11, aged 82.

Baird, Frank Bennett ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1907; team physician of the Philadelphia Athletics for many years; died October 23, aged 72, of carcinoma of the kidney.

Barber, John Phineas, Minneapolis; University of Louisville (Ky.) Medical Department, 1886; member of the American Medical Association; served on the staffs of St. Mary's and Deaconess hospitals; died October 13, aged 93.

Bate, James Robert, Tallahassee, Fla.; Meharry Medical College, Nashville, Tenn., 1931; died recently, aged 50, of essential hypertension.

Beckford, Henry Shedd ⊕ Lieutenant Colonel, U. S. Army, retired, Vancouver, Wash.; Dartmouth Medical School, Hanover, N. H., 1899; served during World War I; entered the medical corps of the U. S. Army as a major in 1920; promoted to lieutenant colonel in 1937; retired Oct. 31, 1938; died October 28, aged 76.

Bianchini Vincent Anthony, Cranston, R. I.; Boston University School of Medicine, 1934; member of the American Medical Association; served during World War II; on the staffs of St. Joseph's Hospital and Roger Williams General Hospital; died suddenly October 8, aged 41.

Bluhm, Kilian Kalonymos, New York; Universität Heidelberg Medizinische Fakultät, Baden, Germany, 1916; specialist certified by the American Board of Psychiatry and Neurology; member of the American Medical Association and the American Psychoanalytic Association; died October 6, aged 60.

Bowker, Alphonso Varion, Athol, Mass.; University of Vermont College of Medicine, Burlington, 1879; for many years a member of the school board, served as associate medical examiner in the district and a member of the board of health; died October 9, aged 93, of carcinoma of the prostate.

Brown, George W., Raeford, N. C.; Kentucky School of Medicine, Louisville, 1898; member of the American Medical Association; served two terms in the state legislature; for many years chairman of the county board of education; formerly mayor and coroner; died October 16, aged 78.

Cabell, Abram L., Terre Haute, Ind.; Howard University College of Medicine, Washington, D. C., 1895; member of the American Medical Association; died in Culver October 6, aged 84, of cerebral hemorrhage.

Cannon, Clair R., Ellsworth, Wis.; Marquette University School of Medicine, Milwaukee, 1913; member of the American Medical Association; died November 3, aged 59, of coronary thrombosis.

Carter, George Clayburn, Jamaica, N. Y.; Albany (N. Y.) Medical College, 1914; member of the American Medical Association; died in Columbia-Presbyterian Medical Center, New York, October 19, aged 59.

Champlin, Paul Morrow, East Orange, N. J.; Detroit College of Medicine and Surgery, 1914; formerly on the staff of the East Orange General Hospital; served during World War I; died October 24, aged 65, of pleurisy with effusion and cardiovascular disease.

Christensen, Bryant Elliott ⊕ Fort Bayard, N. Mex.; Cornell University Medical College, New York, 1925; certified by the National Board of Medical Examiners; served during World Wars I and II; affiliated with the Veterans Administration; died October 18, aged 52, of coronary thrombosis.

Clark, John Vincent, Oklahoma City; University of Oklahoma School of Medicine, Oklahoma City, 1939; member of the American Medical Association; served during World War II; affiliated with Capital Hill General Hospital, Wesley Hospital and Mercy Hospital, where he died September 20, aged 36, of subacute yellow atrophy of the liver and duodenal ulcer.

Coller, Granville J., Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1880; died in the Hospital of the Good Samaritan October 24, aged 96, of pneumonia.

Connole, Joseph Vincent ⊕ Wilkes-Barre, Pa.; Jefferson Medical College of Philadelphia, 1912; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staff of the Nesbitt Memorial Hospital, Kingston, and Mercy Hospital, where he died October 15, aged 61, of cerebral hemorrhage.

Cook, Arthur Ellsworth, Randolph, Neb.; Sioux City (Ia.) College of Medicine, 1898; for many years member of the board of education; member of the American Medical Association; past president of the Nebraska State Medical Association; died in Sioux City, Iowa, November 3, aged 80, of coronary thrombosis.

Craig, Samuel Halleck, Philadelphia; Jefferson Medical College of Philadelphia, 1910; died recently, aged 73.

Davidow, Samuel H., Youngstown, Ohio; Jefferson Medical College of Philadelphia, 1920; member of the American Medical Association; on the staff of Youngstown Hospital, where he died October 6, aged 54.

Disque, Andrew A., St. Joseph, Mo.; Central Medical College of St. Joseph, Mo., 1902; member of the American Medical Association; died September 16, aged 73.

Dobson, James Furman, Ridgeway, S. C.; University of Maryland School of Medicine, Baltimore, 1914; served overseas during World War I; president of the Ridgeway Bank; died in Tri-County Hospital, Orangeburg, September 22, aged 59, of cancer.

Dougherty, J. Milburn Sr., Nickelsville, Va.; Kentucky School of Medicine, Louisville, 1893; died September 6, aged 79.

Dunham, Adeline Frances, Cambridge, Mass.; Tufts College Medical School, Boston, 1905; member of the American Medical Association; died September 17, aged 68, of coronary thrombosis.

Dyer, Frank Merritt ⊕ Binghamton, N. Y.; Cornell University Medical College, New York, 1902; fellow of the American College of Surgeons; associated with Binghamton City Hospital and Binghamton State Hospital; consulting surgeon, Ideal Hospital, Endicott; died October 12, aged 78, of carcinoma of the prostate.

Eaton, Chelsea ⊕ Oakland, Calif.; University of Louisville (Ky) School of Medicine, 1926; died in San Francisco October 9, aged 52.

Ehresmann, Joseph John, Richmond Heights, Mo.; St. Louis University School of Medicine, 1905; member of the American Medical Association; died October 20, aged 72.

Evans, John Corliss, Cincinnati; Eclectic Medical Institute, Cincinnati, 1893; for many years associated with the New York Central Railroad; served on the board of education, on the staffs of the Bethesda Hospital and St. Mary's Hospital, where he died October 9, aged 78, of injuries received in an automobile accident.

Farrell, Robert Lawrence, Providence, R. I.; Tufts College Medical School, Boston, 1931; member of the American Medical Association; served in the European theater during World War II; associated with Rhode Island, St. Joseph's, Charles V. Chapin and the Roger Williams General hospitals; died October 3, aged 43, of hypertensive heart disease.

Low, Triumph C., ⊕ Los Angeles; Chicago Homeopathic Medical College, 1897; died September 17, aged 78, of pneumonia.

Lowe, Kenneth Vincent, New Kensington, Pa.; University of Pittsburgh School of Medicine, 1933; on the courtesy staffs of the Allegheny Valley Hospital, Tarentum, and Citizen's General Hospital; died in Columbia Hospital, Wilkinsburg, October 15, aged 42, of coronary occlusion.

McDonough, John Patrick ⊕ Corona Del Mar, Calif.; John A. Creighton Medical College, Omaha, 1920; for many years practiced in Gunnison, Colo.; killed October 5, aged 56, when the automobile which he was driving in Newport Beach was struck by a fire engine.

McDuffie, James Henry, Columbus, Ga.; University of Pennsylvania School of Medicine, Philadelphia, 1916; member of the American Medical Association; past president of the

Muscogee County Medical Society; served in France during World War I; died in City Hospital September 27, aged 62.

Macy, Mary Sutton, New York; New York Medical College and Hospital for Women, Homeopathic, 1904; formerly served on the faculty of her alma mater; medical examiner for the Pennsylvania Mutual Life Insurance Company; died October 15, aged 70.

Mahar, Gregory Doyle, Syracuse, N. Y.; Syracuse University College of Medicine, 1922; member of the American Medical Association, assistant professor of pediatrics at his alma mater; served as health commissioner of Syracuse and as epidemiologist for the city health department; affiliated with St. Joseph and City hospitals; died October 1, aged 58, of bronchopneumonia.

Margoles, Maxon Edward, Milwaukee; University of Wisconsin Medical School, Madison, 1930; on the staff of Mount Sinai Hospital, where he died October 8, aged 44, of coronary disease.

Mason, L. Dudley, Middletown, Ky.; University of Louisville Medical Department, 1902; member of the American Medical Association; served in the medical corps of the U. S. Army during World War I and on the Selective Service Board during World War II; died October 11, aged 74.

Massey, William Walton ⊕ Quincy, Fla.; University of Georgia Medical Department, Augusta, 1911; past president of the Third District Medical Society; on the staff of Gadsden County Hospital; died October 4, aged 62, of coronary occlusion.

Mayfield, James Isaac, Blue Mountain, Miss.; Memphis (Tenn.) Hospital Medical College, 1909; member of the American Medical Association; past president of the Northeast Mississippi Medical Society; for many years college physician at Blue Mountain College; served as president of the Bank of Blue Mountain; died in Baptist Memorial Hospital, Memphis, Tenn., October 12, aged 68, of congestive heart failure.

Middlebrooks, Violet McMillian, St. Petersburg, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; died October 5, aged 73, of renal insufficiency and renal calculi.

Moore, Dudley A., Lander, Wyo.; Sioux City (Ia.) College of Medicine, 1906; formerly associated with the Indian Service; died September 8, aged 71, of hemorrhage due to gastric ulcer.

Musante, Joseph Bernard, Glen Cove, N. Y.; University and Bellevue Hospital Medical College, New York, 1920; died in the North Country Community Hospital, October 3, aged 60, of cirrhosis of the liver.

Mutschler, Louis H. ⊕ Merion, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; fellow of the American College of Surgeons; consulting surgeon, Hospital of the Protestant Episcopal Church, where he was chief surgeon for many years; formerly surgeon of Philadelphia Orthopedic Hospital and Infirmary for Nervous Diseases and St. Christopher's Hospital for Children, Philadelphia; at one time associated with the Philadelphia Rapid Transit Company; died October 2, aged 78, of pneumonia.

Plummer, Orlay Edward ⊕ Rawlins, Wyo.; Emory University School of Medicine, Atlanta, 1931; formerly vice president of the Carbon County Medical Society; member of the American Association of Railway Surgeons and the Pacific Association of Railway Surgeons; served in the European theater during World War II; died September 26, aged 49, of hypertension.

Porter, Leroy Valentine, Altoona, Iowa; Drake University Medical Department, Des Moines, 1900; died in Woodward October 19, aged 78, of cancer.

Preston, Anna Louisa, Marietta, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896; died August 29, aged 87.

Price, Jerry Clay ⊕ Los Angeles; Tulane University of Louisiana School of Medicine, New Orleans, 1928; member of the Association for the Study of Internal Secretions; formerly associated with the Neurological Institute of New York in New York; died in Good Samaritan Hospital September 24, aged 46, of cancer.

Richards, George Henry ⊕ Sioux Falls, S. D.; Trinity Medical College, Toronto, Canada, 1904; served on the staff of the Veterans Administration Center; died in Ione, Wash., October 11, aged 71, of cerebral hemorrhage.

Rochester, John Robert Fountain, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1900; for many years on the staff of Women's Homeopathic Hospital; died September 14, aged 77.

Roeber, William John, Winters, Calif.; University of the City of New York Medical Department, New York, 1892; formerly practiced in Newark, N. J., where he was associated with Lutheran Memorial and St. Michael's hospitals and the Hospital of St. Barnabas and the Hospital for Women and Children; died September 26, aged 79.

Townsend, Charles Kennard ⊕ Arkadelphia, Ark.; Tulane University of Louisiana School of Medicine, New Orleans, 1915; served during World War I; died September 20, aged 60, of cerebral hemorrhage.

Tripp, Leroy Richard ⊕ Washington, Iowa; State University of Iowa College of Medicine, Iowa City, 1909; past president of the Woodbury County Medical Society; died September 20, aged 64, of bronchopneumonia and multiple sclerosis.

Vigeland, Jorg G., Brinsmade, N. D.; Milwaukee Medical College, 1910; died recently, aged 74.

Ward, Edgar Ewell, Dallas, Texas; Meharry Medical College, Nashville, Tenn., 1915; president of the Excelsior Life Insurance Company; died September 27, aged 58, of heart disease.

Warlick, Henry Clinton, Bluefield, W. Va.; University of Maryland School of Medicine, Baltimore, 1918; died in Lexington, Ky., recently, aged 57, of cerebral hemorrhage.

Weigel, Bernard John, Gorham, Kan.; John A. Creighton Medical College, Omaha, 1917; formerly surgeon in the U. S. Public Health Service reserve; served on the staff of the Russell City Hospital in Russell; died September 15, aged 54, of injuries received in an automobile accident.

Westly, Soren S. ⊕ Manly, Iowa; State University of Iowa College of Medicine, Iowa City, 1909; president of the Worth County Medical Society; vice president of the staff of Mercy Hospital in Mason City; died October 21, aged 68, of heart disease.

White, George Floyd, Cranston, R. I.; College of Physicians and Surgeons, Boston, 1905; formerly school committeeman; served on the courtesy staff of Roger Williams General Hospital, Providence, where he died September 23, aged 71, of arteriosclerotic heart disease, pyelonephritis and uremia.

Wilker, William Fawthrop ⊕ Iola, Wis.; State University of Iowa College of Medicine, Iowa City, 1928; formerly practiced in New York, where he was affiliated with the Lenox Hill Hospital; died September 30, aged 47, of coronary thrombosis.

Wills, William Judy ⊕ Springfield, Mo.; Beaumont Hospital Medical College, St. Louis, 1901; an Associate Fellow of the American Medical Association; member of the American Urological Association; served overseas during World War I; died in St. John's Hospital September 24, aged 75, of injuries received in an automobile accident.

Wilson, Thomas Phillip, St. Louis; Washington University School of Medicine, St. Louis, 1929; served during World War II; on the staff of St. Luke's Hospital; died October 4, aged 45, of coronary disease.

Wimmer, George Glenn ⊕ Mount Etna, Ind.; Beaumont Hospital Medical College, St. Louis, 1899; served during World War I; died in the Huntington (Ind.) County Hospital October 13, aged 75.

Wood, Samuel Houston ⊕ Jackson, Miss.; Chicago College of Medicine and Surgery, 1917; served overseas during World War I; on the rating board of the Veterans Administration; died in King's Daughters Hospital, Yazoo City, October 20, aged 58, of coronary thrombosis.

Wright, Elmer D., ⊕ Seymour, Ind.; Physio-Medical College of Indiana, Indianapolis, 1900; died September 25, aged 76, of chronic glomerulonephritis.

Wrinkle, Thomas D., Springfield, Mo.; Ensworth Medical College, St. Joseph, 1887; member of the American Medical Association; died October 11, aged 93.

Young, Josephine Estabrook, Evanston, Ill.; Northwestern University Woman's Medical School, Chicago, 1896; formerly on the faculty of her alma mater and Rush Medical College in Chicago; died October 4, aged 84, of cerebral hemorrhage.

Young, Lemon Randle, Indianapolis; Flint Medical College of New Orleans University, 1905; died September 26, aged 72, of cerebral hemorrhage.

Zander, Paul A., Kankakee, Ill.; Ludwig-Maximilians-Universität Medizinische Fakultät, München, Bavaria, Germany, 1908; member of the American Medical Association; on the staff of the Kankakee State Hospital, where he died September 23, aged 67, of uremia and diabetes mellitus.

Library Association Conference

Role of the Medical Library.—During the Annual Conference of the Library Association held recently in London, a meeting of the medical section was arranged at the Wellcome Research Institution, on September 20, to discuss the role of libraries in the advance of medicine. The chair was taken by Mr. W. R. Le Fanu, librarian of the Royal College of Surgeons. Sir Cecil Wakeley, the president of the college, said that the conference celebrated the centenary of the public library movement in Great Britain. Many medical libraries, of course, were much more than a century old, and they varied greatly in type and function. Many attempts have been made to coordinate the activities of various libraries. More than 40 years ago, when he first came to Oxford, Sir William Osler founded a Medical Library Association of Great Britain, but it proved short lived. Twenty years later Sir D'Arcy Power promoted a measure of cooperation among the medical libraries of London; the Royal Society of Medicine had organized, with the Rockefeller Foundation, the Central Medical Bureau, to act as a clearing house for readers' inquiries, to obtain the necessary literature from associated libraries and pass it on to all parts of the world in photographic reproduction.

The medical section of the Library Association founded in 1947 acted as a link between medical libraries and provided a forum for the discussion of common problems. Services to readers rather than conservation of books was the keynote of library work. The opportunity had therefore been taken to invite a number of leading representatives of varying interests to give their views on the present state of medical libraries and on the most urgent needs for their improvement.

Library Services for the Research Worker.—Dr. C. H. Kellaway, director in chief of the Wellcome Research Institution, said that, in general, medical research was a continuous process, an accumulation of facts until the time was ripe for their coordination and for the making of some generalization on which further research could be based. It was rare for scientific discoveries to break entirely new ground, and it was part of the library service to make sure of the connecting links. He emphasized the onus on the research worker himself to make a critical study of the relevant literature. He pointed out that one commonly found papers describing observations and results which, unknown to the writer, had been published some years before. However, he went on to point out the values of this repetition of earlier work, which was scarcely ever done by a worker of ability without some new angle of truth being brought into view. He also pointed out the difficulty of maintaining an efficient library service when units of an organization were scattered over a considerable area.

Role of the Librarian.—Dr. Hugh Clegg, editor of the *British Medical Journal,* said that medical librarianship was now a highly skilled profession for which an exacting training was necessary. A library that was solely a storehouse for books and periodicals had only a limited use for those ultimately responsible for the advance of medicine. The storehouse must be converted into something dynamic, and the instrument for this purpose was the trained librarian. He quoted the thirteenth edition of the Encyclopaedia Britannica (1926), which states that libraries are now coming to be regarded more and more as workshops. He emphasized the librarian's task of the collection of periodicals. It was an onerous one, especially now that textbooks were out of date as soon as they were published and the periodical had become more and more important.

Library Users.—Mr. Zachary Cope, a London surgeon, spoke as a library user who had received the most ungrudging help from medical libraries. He said libraries could diffuse medical knowledge more quickly than any other facility. The speaker said that he had recently had the duty of reviewing some German textbooks on surgery and had been surprised at the lack of knowledge concerning some things which were commonly known in this country, the use of penicillin for example. Many German libraries had been destroyed during the war, and free communication had been interrupted. Although much was being done to remedy these evils, the effect of the literature was still woefully apparent. The part of the library which was most valuable to the research worker was that concerned with current periodicals. There were 15,000 or more medical journals, and it was impossible for any library to carry more than a small proportion. He deplored the fact that young men depended on a librarian to look up their references for them. To look up one's own reference was a valuable means of education.

Prof. E. C. Dodds spoke of the Library of the Royal College of Physicians, part of which dated from the Great Fire and had an uninterrupted existence from the sixteenth century. At that library there were works on every subject—not only on medicine, but on astrology, theology and oriental philosophy. The library was now being carefully surveyed by the college authorities. He thought this extraordinary collection of books would be of great value to research.

Mr. W. A. Lees spoke of the librarian of an old provincial library founded by a few physicians and surgeons in Liverpool, about 170 years ago. He said that in these changing days it was difficult to foresee what might happen to the older established libraries depending for their income on subscriptions of members. This was how they would continue to play their part now that new libraries had been set up in teaching and other hospitals by the Regional Hospital Boards. He thought that there should be some method whereby these collections, made many years ago, could ke kept up to date and be useful for succeeding generations.

Medicine in the Public Library.—Mr. Geoffrey Stephens, librarian of the Borough of St. Marylebone, described an important scheme whereby each of the 28 London boroughs had accepted responsibility for specializing in their libraries in one particular branch of literature. Marylebone, probably because it included Marley Street and about twice as many hospitals as any other borough, as well as central pharmacies and orthopedic establishments, had been asked to specialize in medicine. The speaker had been reluctant to undertake this, foreseeing morbid curiosity on the part of the lay public, but a nucleus of the medical section had been created. Previous experience had shown that the demand was chiefly for preclinical literature of some standard encyclopedias. Requests came mainly from hospital nurses, medical students and those working in medical ancillary occupations. He thought the policy was a good one, although it had been better received than he, in his reluctance, had thought possible. Several of the speakers criticized public libraries specializing in medical literature. It was pointed out that it would be absurd to expect library committees, unless there were medical persons on them, to build up a useful section.

The Bibliophile Service.—Mr. G. R. Edwards, Secretary of the Royal Society of Medicine, said that the establishment of libraries in hospitals, teaching or otherwise, was an excellent idea. Facilities provided all over the country were woefully inadequate. The papers appearing in less easily available sources and the bibliophile documentation service which the Royal Society of Medicine had sponsored might be recommended.

A small nonprofit fee was charged as the service was extended from Reykjavic to Singapore. Hardly any day of the week passed without a film strip's being dispatched from London conveying information to medical persons in distant parts of the world, information which was unobtainable in their local libraries. Mr. Edwards applauded what had been said of the necessity of training medical librarians. Speed in obtaining the desired information was of great importance. In conclusion, the chairman said that all problems concerning the subject, including possibly the joining of forces of the libraries of smaller medical societies and the restoration of hospital libraries, were receiving careful consideration.

FLORENCE, Oct. 10, 1950.

International Meetings

At the International Meetings of Verona, reported on in a previous letter, Prof. E. Moniz of Lisbon, Nobel Prize winner, spoke on present day neurosurgery, with special regard to contributions made by the Portuguese. Sicard, through intraspinal injection of iodized oil, achieved precise location of compression of the medulla oblongata, but for cerebral tumors the problem was more serious. While Dandy's ventriculography was known, the method entailed risk for the patient. Moniz conceived the technic of tumor location by rendering the cerebral arteries opaque, to permit observation of the deviations of the arteries. The initial problems were (*1*) to obtain a liquid opaque to roentgen rays that could be injected without danger into cerebral circulation, (*2*) to ascertain whether the internal carotid artery tolerated the needle puncture and the injected substance and (*3*) to determine the possibility of temporary blocking of blood flow to the brain, without danger to the patient.

After many experiments, Moniz and his co-workers succeeded in obtaining arteriograms of arteries of the brain in dogs (in collaboration with Prof. Almeida Lima) and cerebral arteriograms in human cadavers, which revealed the normal distribution of arteries. After this experimental work, cerebral arteriography was performed clinically for the first time. At first sodium iodide was used as the contrast medium and then colloidal suspension of thorium dioxide (thorotrast®). This was subsequently replaced by easily eliminated iodine compounds. Cerebral tumors were diagnosed by this technic; the circulation of some tumors was observed and their volume determined. Also cerebral angiomas could be demonstrated and the differential diagnosis of cerebral aneurysms could be made.

The speaker was awarded the Nobel Prize for his work on prefrontal leukotomy. He stated that the reactions which take place at the synapsis are those which determine the mental makeup, and disturbances of these reactions cause the so-called functional psychosis. The concept of prefrontal leukotomy arose from the supposition that severing of diseased junctions would alter the pathway of the impulses, permitting cure of the mentally sick. The frontal lobes were chosen as the site of leukotomy because their function is linked, although vaguely, to the human mind. In the first 20 patients operated on by Prof. Almeida Lima in collaboration with Prof. Moniz, one third of the patients were cured, another third were improved and a third were unimproved. According to the speaker, further progress is needed in this field.

Treatment of Typhoid and Brucellosis

At the session of the Academy of Sciences of Ferrara, presided over by Professor Dogliotti, reports on modern treatment of typhoid and brucellosis were presented. Drs. Gualandi, Pederzini and Temussi reported on results they obtained in treatment of brucellosis with paraaminosalicylic acid and its calcium salt. The drug was administered by mouth in daily doses of 8 to 10 Gm. for 8 to 10 days. Defervescence by crisis occurred on the second or at the latest on the seventh day, with considerable improvement of the general condition. Drs. Sandri and Cavicchi reported their results with the use of chloramphenicol and aureomycin in typhoid, paratyphoid A and brucellosis. Both drugs were administered in doses of 0.25 Gm. every three hours, and the treatment was continued for a few days after normal temperatures were obtained. In brucellosis, apyrexia was obtained on the second or third day of treatment with aureomycin. In typhoid and paratyphoid A treated with chloramphenicol, there was a rapid drop in temperature followed by a definite improvement of the general condition and permanent cure. The patients with paratyphoid A who were treated initially with aureomycin did not show improvement, but recovery resulted from combined treatment with chloramphenicol. Drs. Ruberti and Neri reported on patients with typhoid treated with chloramphenicol; they observed a drop in temperature between the seventy-second and ninety-sixth hour after the start of treatment. They concluded, however, that such therapy does not influence the pathological process or prevent relapses and perforations. Drs. Magri and Melli reported on 13 cases of brucellosis treated with a daily dose of 1 Gm. of aureomycin. Defervescence was rapid and definitive in the majority of the cases.

TURKEY

(From a Regular Correspondent)

ANKARA, Nov. 15, 1950.

The 1950 Census

When the first census was taken in Turkey, in 1927, the population was 13,648,270; the second census, in 1935, showed an increase to 16,158,018; the third, in 1940, to 17,820,950, the fourth census, in 1945, to 18,860,222 and the fifth, taken on Oct. 22, 1950, to 20,902,628. Immigration accounts for an increase of about 20,000 persons. Istanbul, the largest city, has a population of 1,001,002, the capital, Ankara, has 285,143, Izmir has 230,473, Adana has 118,247 and Bursa has 101,096 inhabitants. The birth rate, 40-42 per thousand, is highest in rural communities, which contain 73 per cent of Turkey's population. The natural increase during the last five years is 21.3 per thousand. Birth control is prohibited by law since the 1930 public health act. Twenty-five years of public health work has raised the nation's standard of health, and the effect of untoward conditions resulting from the war have gradually disappeared.

Turkish Whooping Cough Vaccine

Epidemics of whooping cough occur in Turkey usually after an epidemic of measles in the spring. When in August 1948 an epidemic of whooping cough in the environs of Izmit (Smyrna) was reported, the Ministry of Health appointed Dr. Sabahaddin Payzin and Dr. Necmeddin Akyay from the Refik Saydam Institute of Hygiene at Ankara to administer the vaccine that had recently been prepared at this institute and to report on the results. Of the 646 children vaccinated 12, or 2.9 per cent, were 6 months old; 60, or 9.2 per cent, were 6 to 12 months old; 182, or 24 per cent, were 1 to 3 years old; 204, or 31.8 per cent, were 4 to 5 years old; 141, or 20 per cent, were 6 to 10 years old, and 30, or 4.6 per cent, were 10 to 20 years old. The patients received doses of 0.25, 0.50, 0.75, 1.00 and 1.5 cc. of vaccine with two to three day intervals. Of the 646 patients, 480, or 75 per cent, recovered. In children 1 to 5 years old, vomiting, whooping and coughing disappeared after the second and third vaccination; in children 5 to 10 years old, they disappeared somewhat later. Untoward reactions have not been observed. There was one death, caused by pneumonia, a complication of measles. Forty-two, or 6.5 per cent of the patients failed to return for vaccination. The vaccine was also used for preventive inoculation of 32 children; all remained immune during the epidemic. The Turkish whooping cough vaccine was prepared from domestic strains and used soon after preparation.

Central Anti-Tuberculosis Institute in Istanbul

An agreement has been reached by the World Health Organization of Geneva and the Ministry of Health and Social Assistance of the Turkish Republic according to which physicians and nurses from Middle East countries take a postgraduate course in antituberculosis work at the Central Anti-Tuberculosis Institute in Istanbul. WHO will furnish the equipment and will be responsible for the remuneration of the teaching staff and traveling expenses for participants in the course. The center is to function under the auspices of the World Health Organization for a limited time, and then it is to be an integral part of the Ministry of Health and Social Assistance and is to be directed by Turkish specialists. Currently the courses are directed by Dr. Etienne Berthet, WHO turberculosis consultant.

After completion of the theoretical and practical course in which almost all Middle East countries will be represented, the participants are to engage in antituberculosis work in their respective countries. Last summer Turkish physicians and nurses took a three month introductory course, which was the start of special training for Turkey's antituberculosis work. The Ministry of Health has required 95 Turkish physicians to take the first course, which is now in session. The theoretical course will be conducted by Ord. Prof. Tevkif Saglam of Istanbul University. The 500 bed tuberculosis sanatorium at the Heybeliada in the Sea of Marmara, the Haydar Pasha tuberculosis hospital, the 500 bed tuberculosis hospital at Yedikule, Istanbul, and the 14 tuberculosis dispensaries (to which 6 are soon to be added) will provide opportunity for practical experience.

The first society for the prevention of tuberculosis was established in Istanbul in 1916, but because of the prolongation of the war and the many untoward conditions after it, the society was short lived. Actual tuberculosis control work started in 1923 with the founding of the Izmir Society for the prevention of tuberculosis and the restablishment of the Istanbul Society in 1926. In 1931 the tuberculosis death rate in Istanbul was 203 per 100,000; it had decreased by 1939 to 187, but war conditions brought the rate up again. Ord. Prof. Tevkif Saglam has for more than 15 years directed the tuberculosis prevention work in Istanbul.

SPAIN

(From a Regular Correspondent)

Madrid, Oct. 1, 1950.

Roentgenography of the Small Intestine

Dr. C. Marina Fiol and his co-workers have published, since 1941, a series of roentgen studies on the pathology of the small intestine. It was discovered that in cases of superficial enteritis the passage of the contrast substance through the small intestine is either normal or delayed, contrary to the general opinion that passage is accelerated in this condition. They described an intestinal disorder characterized by effusions that generally coincide with emotional moments and that occur in labile young persons who suffer great anxiety and mental conflict. Roentgenologically, this syndrome is characterized by a rapid passage of the contrast substance through the small intestine. Dr. Fiol believes that this syndrome is purely functional. It is due to a vagal hypertonia. He calls it neurointestinal asthenia. The name has the same significance with respect to the small intestine as neurocirculatory asthenia has with respect to the circulatory system. Fiol and his co-workers also studied stagnation in the lower angle of the duodenum, which they believe is not due to functional stricture but to a superficial inflammation similar to that which occurs in sprue. They described superficial ileitis, which develops with clinical symptoms similar to those of appendicitis. In 1941, the authors described a series of roentgen areolar images of the terminal ileum that show diffuse hyperplasia of the lymphatics of the intestine. (This roentgen aspect was described by American roentgenologists in 1945.) The authors consider that this syndrome is physiological in children and pathological in adults. They called it follicular ileitis, a name used by German pathologists who saw this type of hyperplasia only in the cadavers of children dying of diarrhea. The authors point out that Crohn's disease is rare in Spain. They note that various factors may play a role in the development of this syndrome. Changes in the ileum with rigidity and loss of the structural characters of the mucosa, which the author calls granulomatous ileitis, is frequent in Spain. This condition probably constitutes the early phase of Crohn's disease. The authors described, also, a clinical form of ileitis following typhoid, characterized by lesions in the terminal segment of the ileum. In one patient post-typhoid ileitis was followed by Crohn's syndrome. The most important roentgen observations reported are those by which an early diagnosis of intestinal tuberculosis is made. According to the authors, the terminal segment of the ileum is most frequently involved by early lesions. In many cases a nodule, the "alarm nodule," is observed in the upper external portion of the ileum. This nodule, caused by hyperplasia of Peyer's patches, becomes ulcerous. Pictures of round and annular tuberculous ulcers were obtained by the production of pressure on the terminal segment of the ileum. The initial lesions often disappear after a short time. In other cases, however, they are the starting point of large tuberculous lesions, the diagnosis of which can be made only by evidence of the classic roentgen aspects of intestinal tuberculosis, namely, lesions in the cecum and in the ileocecal sphincter and the presence of Stierlin's radiologic sign. Fiol has also carried on clinical and roentgen studies on sprue and other syndromes of the small intestine that are secondary to diseases of other organs and apparatus. He discusses the mechanism and the roentgen and clinical aspects of these diseases in his book "Roentgenography of the Small Intestine," recently published in Spain.

Psychosomatic Pathology

A school of psychosomatic pathology has begun to function in the department of neuropsychiatry of the General Hospital of Madrid. Professor J. J. López Ibor, head of this department, is also director of the school. Weekly sessions are held at which various related subjects and illnesses are discussed. Professor López Ibor and his associates are trying to establish the principles for a general psychosomatic pathology. If the large number of articles on the subject, especially those of the American School, are analyzed, the psychic profile that accompanies somatic diseases is evident. A group of somatic diseases, such as arterial hypertension, hyperthyroidism, migraine, anuresis and mucomembranous colitis, constitute the true nucleus of psychosomatic pathology. Among the elements of the psychological profile, the aggressive tendencies, a perfectionist tendency and tendencies of an obsession type are dominant. Anxiety is fundamental in all cases. A profound psychopathological interpretation of the character of patients with any of the aforementioned diseases shows that all have an "anxiety structure." The aggressive tendencies, the obsessions and the phobias in these patients are outward manifestations of this anxiety structure. Besides these, other work in progress includes a psychopathological study of marihuana addicts and studies of the indications for transorbital leukotomy.

Prof. López Ibor is official speaker at the next International Congress of Psychiatry. He will speak on "Indications of Biologic Methods in Psychiatric Diseases." Dr. Guera, head of the psychology department of the same clinic, is also official speaker at the congress. He will speak on "Methods of Projection in the Psychiatric Clinic."

BRAZIL

(From a Regular Correspondent)

RIO DE JANEIRO, Nov. 10, 1950.

Intestinal Schistosomiasis

Manson schistosomiasis, or intestinal mansoniasis, is a more important health problem in Brazil than it seemed five years ago. Exact knowledge of the prevalence of the principal helminthiases throughout this large country is still fragmentary, even for the most important ones, i. e., hookworm disease and intestinal schistosomiasis. The national department of health in 1947 planned a five year uniform survey of diseases caused by helminths, to ascertain their geographic distribution and incidence throughout the country. Because of the limited personnel and appropriations, it was decided to restrict the survey to school children (7-14 years of age) of localities of 1,500 inhabitants or more. A recent report by Drs. A. Barca Pellon and Isnard Teixeira describes the work done during the first three years of the survey, which included 11 of the 20 states of Brazil, in the northeastern and middle eastern Atlantic states, represented by 889 localities with a present population of over 4,500,000. The first part of the survey was begun in July 1947 in the northeastern states of Alagoas and Sergipe, already known as important foci of the infestation, and was extended, in 1948, to Pernambuco and Minas Gerais (first half), and in 1949 to Maranhão, Piauí, Ceará, Rio Grande do Norte, Paraíba, Espirito Santo and Minas Gerais (second half), to be concluded on June 24 of this year, in the state of Bahia. For the performance of all phases of this enormous survey of the eastern third of the country, the cooperation of local health and educational authorities, mayors, teachers, postmasters and railroad station masters was secured. The technic used for the microscopic examination of the stools was the spontaneous sedimentation concentration method of Hoffmann, Pons and Janer, already extensively tested in Brazil by J. A. Meira and Vianna Martins.

Completion of the first part of the School Helminthologic Survey, as it is currently called, took 757 days of effective work, costing 3,061,627.30 Brazilian cruzeiros, the equivalent of about $153,000, for the examination of 440,786 school children, an average of 582.28 persons examined per day and 495.26 per locality. The average cost per child examined was about 34.7 cents. Of the 646,409 children registered in the schools of the 889 localities surveyed, 440,786 were examined, or 68.19 per cent, this percentage ranging from the minimum of 46.26 for the 30 localities of the state of Sergipe to 81.68 for the 221 localities of the state of Bahia. Of the 889 localities included in the survey, 611 had cases of infestation. The minimum number of cases in a locality was 7, in the state of Maranhão, and the maximum 211, in the state of Bahia. The total number of school children with infestation was 44,477, or a general index of positivity of 10.09 per cent for the sample surveyed, this index ranging from the minimum of 0.04 per cent for the state of Piauí (four cases in 10,424 children examined) to the maximum of 29.80 per cent for the state of Sergipe (5,134 cases in 50,977 children examined). There were, however, large variations of the index of positivity within each state: thus, in Sergipe, for example, where the index was maximum (29.80), it varied, for the 30 localities with positive cases, from 1.30 to 91.34, for the locality Rosario do Catete in the central part of the state, one of the five districts into which Sergipe is divided. Even by districts, which in this small state include an average of six localities for each, the variation of the positivity index is also great, decreasing from 62.82 for the central district, to 28.49, 21.62, 12.94 and 3.19, for the coastal, west, middle and lower São Francisco River districts, respectively.

Plotted on the map of the country, these results show that intestinal schistosomiasis infestation forms small more or less sparse foci in the northern states of Maranhão, Piauí, Ceará and Rio Grande do Norte (with a general positivity index for the zone of 1.07, which varied from 0.04 (Piauí) to 2.32 (Rio Grande do Norte), to take a more regional character of large zonal foci, in the states of Paraíba, Pernambuco, Alagoas, Sergipe and Bahia, in the bulge of northeastern Brazil, with a general positivity index of 19.42, ranging from 7.49 for the state of Paraíba, to 25.09 for Pernambuco and up to 29.80 for Sergipe. The area of endemicity of the parasitosis is broken by the valley of the São Francisco River, so that, in the state of Bahia, the general index for the whole region of this valley, the western plateau and the southern part of the state, close to Minas Gerais, falls to 3.81. For the state of Minas Gerais itself, more to the south, the general index is 4.92, with 0.04, in the southern zone, and 12.09, 16.62 and 30.02 in other zones of the same state.

Of the 611 localities with positive stools for ova of the parasite, only 381 showed positivity indexes higher than 4 per cent. If one takes into account that the average number of children examined per locality was 495.26, this minimum incidence would correspond to at least 19 cases of infestation per locality, which is probably a number of cases sufficient to characterize the existence of a focus, since those cases would involve children of school age. The incidence is significantly higher in male than in female children and higher in children living in rural districts than in towns. Typical of these differences are the figures for Sergipe, the state with the highest general positivity index: 32.98 against 27.15 for the two sexes and 36.46 to 29.37 for the character of the district of residence.

Erythrocyte Values of Adolescent Workers in Rio de Janeiro

Dr. Rubens Bastos of the Division of Industrial Hygiene, Ministry of Labor, published a report on the study of the erythrocyte values of adolescent workers (14 to 17 years) of both sexes, with the establishment of the curves of age distribution of the corpuscular values within those age limits. The report represents another Brazilian contribution to the knowledge of the variation of the red cell characteristics in connection with some social, geographic and anthropologic factors. The study was based on a group of 745 subjects of both sexes (471 males and 274 females) from 14 to 17 years of age. All were born in Rio de Janeiro or had lived in that city several years. Of the 471 males, 301 were white and 170 colored; of the 274 females, 133 were white and 141 colored. These adolescent workers were employed in industrial establishments (textiles, glass, rubber, metal foundries, carpentry), and all had been previously subjected to a simple medical examination, including a roentgenogram of the chest. The main results of the study may be summarized as follows: the mean corpuscular hemoglobin concentration is identical in both sexes at age 14 and is practically the same, but begins to be different for the boys, at ages 15, 16 and 17. This difference is very slight between ages 14 and 15 and between ages 16 and 17, but is larger and significant between these two groups. The mean corpuscular volume and the mean corpuscular hemoglobin present a similar variation. Contrary to the results of Milan and Muench, no significant differences were observed between white and colored persons. A last important point is represented by the age at which the erythrocyte value in the male is stabilized. In the adult man, in Rio de Janeiro, the mean corpuscular hemoglobin concentration is not less than 14.54 per cent, which is the average for the 17 year group.

CORRESPONDENCE

TOUR OF THE FAR EAST

To the Editor:—Having just completed (Oct. 30, 1950) a six weeks' tour of the Army and some of the Navy and Air Force medical facilities in the Far East, including those in the Inchon-Seoul area, I feel that the impressions gained might be of interest to the profession, especially to those who served in World War II and those who anticipate military service. My tour as Consultant in Internal Medicine to the Surgeon General of the Army afforded the opportunities of observing problems on the spot, of seeing problem cases, of making ward rounds, of participating in conferences and briefings, of getting the "low down" from former students as well as from those with whom I had served in the South Pacific in World War II, of discussions with head nurses and dieticians and of having the Army Theatre Consultant in Internal Medicine for the Far East, Col. Francis Pruitt, accompany me throughout the tour. It is on these opportunities that the following impressions of the functioning of the United States Army Medical Corps in the present conflict are based:

1. The personnel of the military services received and are receiving superior medical care, which is conducted at times under most trying circumstances. Medical personnel and supplies in medical facilities in Japan were grossly depleted to provide immediate treatment of the wounded in the forward areas. Countless lives were saved by the evacuation of patients by air to hospitals in Japan. As of October 9, more than 17,000 had been transferred in this manner. Patients leaving Pusan by air were in a modern hospital, the 118th Station Hospital at Fukuoka, in one hour. A considerable number of patients were picked up in forward positions by helicopters. It is my opinion that Mr. Drew Pearson was misinformed or uninformed concerning the military medical services in the Far East. Otherwise, his public statements would have been closer to fact.

2. The number of doctors and nurses were inadequate until about October 5. Momentarily the medical staff of the Army Tokyo General Hospital of 1,200 beds (expanded to 2,000 beds later) was reduced to seven physicians—a measure necessary to provide emergency care at the front. A maximum of efficiency was made possible by the improved policy of appropriate assignment of specially trained personnel when this was practicable—a policy which is kept up to date by the functioning of the theatre consultants.

3. A great medical tragedy was avoided by having, on immediate call, physicians taking residency courses in military and civilian hospitals under the auspices of the Army. When the peak demand for doctors was reached, more than 50 per cent of the physicians in this theatre were physicians whose residencies had been abruptly interrupted. At one time all the medical officers except the commanding officers of five hospitals were physicians whose residency training had been interrupted. It is important for everyone interested in the care of military personnel to know that, had it not been for the Residency Training Program adopted by the Army after World War II, our forces would have been faced with the tragedy of a crippling inadequacy of physicians when called on to enter a suddenly precipitated and unanticipated conflict. The unavoidable delay of 90 days in getting reserves into action would have cost many lives, and the care of the sick and injured could not have been anything but inferior. Surely, foresight in training could not have been turned to better advantage.

In an age in which the onset of conflict is likely to be sudden and unexpected a reservoir of physicians with more than average training and available on a moment's notice is invaluable. We will do well to appreciate the sacrifices these young physicians have made and from one who has seen them in action, not for an eight or 10 hour day but until the job at hand was done—days on end with only a few hours' respite—they have my sincere admiration.

4. The absence of serious epidemics. Dysentery, due to Shigella organisms, was common but relatively mild and responded promptly to chloramphenicol therapy. The most serious illness encountered has been Japanese B encephalitis. The mortality ranged from 10 to 15 per cent, and tragic residual manifestations are common. Fortunately the season for this disease ended in October. Hepatitis is endemic but is not a great military problem. Two deaths occurred in one week from this disease when the total number of such patients being treated was approximately 100. The reappearance of a mortality, due to hepatitis, in troops is due, in all probability, to the impaired nutritional and physical state of the patient as a result of combat and not a change in the virulence of the virus. A small number of cases of scrub typhus has been seen.

BANTHINE® IN THE THERAPY OF PEPTIC ULCER

To the Editor:—Various agents (vagotomy, the atropine-belladonna group) have been used to lessen vagal function in the treatment of peptic ulcer. Recently, a new anticholinergic drug, banthine® (beta-diethylaminoethyl xanthene-9-carboxylate methobromide), has been made available to the medical profession for this purpose. The drug is apparently a valuable adjunct to the therapy of peptic ulcer. Only too often in the past has a new therapeutic remedy been enthusiastically received and then as energetically rejected. On the basis of my personal experience with a fairly large series of ulcer patients, I wish to outline the following suggestions regarding the use of banthine.®

1. The amount advocated by Grimson seems too large for most patients. My co-workers and I have found 50 mg., instead of 100 mg., given orally, sufficient. Admittedly, a small percentage of patients tolerate the larger dose.

2. To prevent meal-induced vagal activity, the drug should be given before meals rather than every six hours, although another dose on retiring and one during the night is approved.

3. Since our studies of ulcer patients in the Gastro-Intestinal Clinic of Mount Sinai Hospital have not shown any constant inhibitory effect of 100 mg. of banthine® on gastric secretion, we advocate the concomitant use of alkalis.

4. Except for investigational purposes, we do not consider it fair either to the patient or to the drug to permit an ulcer patient to be treated with banthine® alone without regard to tissue aggression factors, such as an irritating diet, tobacco and alcohol.

5. Occasionally patients with severe nocturnal pains are not relieved by banthine® but do respond to my continuous intragastric drip therapy.

6. Males with present or impending prostatism should not be given the drug. Pyloric obstruction also seems to be a contraindication. A small percentage of patients complain of general malaise and weakness (sympathetic factors?) and cannot tolerate the drug.

[illegible] Medical College
[illegible]
32666

7. The complete loss of symptoms in most patients with uncomplicated peptic ulcer is immediate and gratifying. In my experience no other drug previously used has given such excellent symptomatic results in such a large percentage of patients. It is probable, although this requires further study, that the beneficial effects result either from decreased motor activities or from some degree of sympathetic block.

In our experience, patients may become symptomless and the ulcer heal or not. It is, therefore, imperative that while the patients are being treated with this drug they have repeated radiographic studies. Future studies may reveal that healing occurs when the acid factor is controlled.

Asher Winkelstein, M.D.,

RETIREMENT AT SIXTY-FIVE

To the Editor:—A patient from Waterloo, Iowa, has brought up a point on which I have felt strongly for some time, namely, forced retirement of business executives at the age of 65. I suppose that this practice, which is prevalent in many corporations, has one advantage—it allows earlier promotion of younger men. I am also sure that many men who reach the age of 65 are no longer fit to carry on their duties. I am sure, however, that you will agree with me that one cannot use any age limit as a criterion of when a man is or is not fit to carry on. With the modern advances in medicine, age 65 is no longer considered as old as it used to be. Many men are really in their prime at that age and stay that way for five, 10 or even 20 years more.

It seems to me that a campaign could be started among corporations and in medical schools and other universities to offset previous practices in this regard. In its place, such large institutions might have a committee which would judge as to the fitness of every person as he approaches the age of 65. If the committee decided that a man had all his faculties, he would be kept on in his position as long as he retained those faculties. To avoid possible complaints, this committee should be composed of both older and younger men. As a corollary, such large institutions would do well if they would insist that those approaching the age of 65 should have thorough physical examinations at stated intervals, at least once a year. This would weed out a number who are physically unfit to carry on and would make room for the younger executives.

USE OF SODIUM CHLORIDE SOLUTION FOR SHOCK

To the Editor:—The letter of Drs. Rosenthal and Tabor (*J. A. M. A.* **144**:413 [Sept. 30] 1950) is timely in its emphasis on the need for simplifying the treatment of shock, especially in its early stage. It is regrettable that there is no reference to the outstanding advocate of the use of isotonic sodium chloride solution in large amounts for shock. Dr, Frederick M. Allen, on the basis of his own work and scattered observations in the literature, was the first to introduce tourniquet shock as a standardized laboratory procedure. He was the first to interpret shock as a mixture of physical and toxic factors (*Arch. Surg.* **38**:155 [Jan.] 1939). He advocated isotonic sodium chloride solution as being equal to and sometimes superior to plasma for shock and burns (*Am. J. Surg.* **61**:79, 1943; **62**:80, 1943). The availability of the solution in practically unlimited quantities should be brought to the attention of those charged with the setting up of disaster centers, especially as these will be staffed largely with lay personnel.

SEXUAL EFFECTS OF VASECTOMY

To the Editor:—In the July issue of The Journal there appeared an article by Garrison and Gamble on the effects of vasectomy. I have been interested in the surgical correction of male sterility for the past 30 years and have frequently been confronted with the problems of the patient who has undergone vasectomy; for this reason I feel that some comment on this subject is in order. These authors state that the use of vasectomy has been limited because the average male is apprehensive of a handicap in his sexual life as a result of the procedure. They further state that they performed vasectomy in 23 cases because the couple had "as many children as they wanted or could care for adequately." One patient spoke of a wife "almost crazy with worry." Nineteen other patients were sterilized because of "physical disabilities" of the wife. Kidney disease, diabetes, difficult labor and asthma are mentioned as conditions in the wife which served as an indication for sterilizing the husband. In eight patients the husband was operated on because he had neurosyphilis, diabetes, rheumatism, multiple sclerosis, asthma, blindness or deafness. The authors state that, after an experience of 50 procedures on "unselected mentally normal patients," they found that 47 of the 50 (and, as stated by their husbands, all the wives) were satisfied with the results of the operation.

This subject seems to me to have been dealt with, in this instance, in a rather superficial manner. The surgeon that considers doing a vasectomy for any purpose other than the direct treatment of local disease must know that in practically every state in the Union this operative procedure is considered an illegal one. Furthermore, the patient may sue the surgeon and recover damages under the law, even though he, the patient, has stated under oath that he requested that the operation be done.

The psychic and emotional effects of vasectomy are much greater and more deeply rooted than an analysis of such factors as "effect on libido," "postorgasmal symptoms" and "frequency of intercourse" would indicate. Making a man "safe sexually" has often resulted in marital infidelity, domestic discord, separation and divorce. These experiences are frequent in our records in contrast with those quoted by the authors in their 50 cases.

The average physician may be tempted to recommend vasectomy as the easy and safe way to effect sterilization. The operation is simple, devoid of risk and entails no immediate disability worthy of mention. Such advice should not be given lightly. Most experienced urologists will agree that profound sexual neuroses and imaginative ills often follow vasectomy when it has been performed purely to prevent pregnancy. This is true especially of the private patient and perhaps less so in the clinic patient.

Experienced surgeons will demand more valid indications for male sterilization than those advanced by Garrison and Gamble. In addition, they may wisely insist on neuropsychiatric help in the preoperative appraisal of some of these patients and their problems. I know of no surgical procedure which makes the operator more vulnerable to the complaints of a disgruntled patient than a male "sterilization" that has been done without considered judgment on the part of all concerned.

Vincent J. O'Conor, Professor of Urology,
Northwestern University Medical School, Chicago 11.

The medicolegal aspects of operations to produce sterility were discussed in a statement prepared by the Bureau of Legal Medicine and Legislation and published in The Journal Nov. 12, 1949, page 810.—Ed.

Council on Medical Education and Hospitals

ESTABLISHMENT OF CONFERENCE COMMITTEE ON GRADUATE TRAINING IN SURGERY

By action of the Board of Trustees of the American Medical Association, the Board of Regents of the American College of Surgeons and the American Board of Surgery, a Conference Committee on Graduate Training in Surgery has been established. The purpose of this committee is to formulate uniform standards for residency training in surgery, to sponsor a single inspection service for hospitals offering such training and to approve and publish a list of acceptable residency programs. Lists thus approved by the conference committee will be published in THE JOURNAL and in the *Bulletin of the American College of Surgeons* at periodic intervals. The first of these lists of approved residencies for surgical training appears below.

Hospitals desiring approval of residency training in surgery should make application for inspection on behalf of the Conference Committee on Graduate Training in Surgery to the Secretary of the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

SURGERY

The following services have been approved by the Council, the American Board of Surgery and the American College of Surgeons. Approval for training in hospitals listed in the 1950 Internship and Residency Number (**142**:1204-1211 [April 15]), but not included in this list, will be extended to July 1, 1951, as previously announced. Approval for training in hospitals not listed in the 1950 Internship and Residency Number but included in this list is retroactive to July 1, 1950. Hospitals designated by an asterisk offer approved training in surgery of less than three years' duration, which is integrated with or contributory to a fully approved program.

INTERNSHIPS AND RESIDENCIES

The following internship and residency training programs have been approved since the publication of the list of Approved Residencies and Fellowships in THE JOURNAL, April 15, 1950. A number of hospitals not included in this list have recently been surveyed by representatives of the Council and have been recommended for residency approval. These hospitals will be notified as soon as final action on their applications has been completed. A list of these services will appear in the Hospital Number of THE JOURNAL.

Medical Motion Pictures

Laboratory Diagnosis of Tuberculosis. Parts I, II and IV: 16 mm., black and white, sound. Produced in 1949 by and procurable on loan from United States Public Health Service, Communicable Disease Center, 605 Volunteer Building, Atlanta 3.

The purpose of this series of motion pictures is to aid in teaching the preparation of the Lowenstein-Jensen-Holm egg-potato flour medium for diagnostic cultivation of tubercle bacilli. Recent publicity has focused attention on the importance of roentgenograms of the chest as a means of diagnosing pulmonary tuberculosis. It should be pointed out that this method, though helpful as a screening procedure, is not the final criterion of specific diagnosis of tuberculosis. The finding of tubercle bacilli is the only sure proof.

These films give the complete story of all the steps needed for specific bacteriologic identification of the tubercle bacillus.

Part I: Preparation of a Culture Medium. Showing time 14 minutes.

This film presents in great detail the preparation of the Lowenstein-Jensen-Holm egg-potato flour medium which is generally accepted as one of the most satisfactory for this purpose, because it can be easily prepared even in a small laboratory, it inhibits growth of contaminating bacteria, it supports growth of all three strains of tubercle bacilli (human, bovine and avian) and it permits preliminary identification of each strain by colony appearance.

Part II: Preparation of Sputum Specimens. Showing time 16 minutes.

This section gives the step by step technic of preparation of the sputum specimen for cultivation. Exact strain identification is extremely important for prognostic purposes.

Part III is still in production.

Part IV: Typing of Tubercle Bacilli by Animal Inoculation.

This film illustrates the technic of animal inoculation and eventually of the autopsy and the interpretation of the observations for the purpose of strain determination. It is commendable that emphasis is placed on sources of error. A broken test tube is used as an illustration of possible danger, and the importance of sanitary precautions is clearly shown. The bacteriologic technic is excellent and will impress the attentive observer. The technics are simple, easy to follow and require no elaborate instruments.

Only a color film can bring out certain features that will of necessity be missed in a black and white film. For example, the fine details of the postmortem observations in the animals are not very clear in part IV. With this one exception this series of pictures is a good illustration that black and white films can still be used to great advantage. This series is well organized for teaching and is highly recommended for teaching of bacteriologists, medical students, public health laboratory technicians and students of medical technology. Clinical pathologists and teachers of bacteriologic technic will find this production most useful and interesting. The photography and narration are excellent.

Intra Oral and Pharyngeal Structure and Their Movements. 16 mm., color, sound, showing time 18 minutes. Produced in 1950 by the Veterans Administration, Department of Medicine and Surgery. Procurable on loan from Chief, Medical Illustration Division, Research and Education Service, Veterans Administration, Washington, D. C.

This film shows the physiological activity of the tongue, soft palate and epiglottis in a patient who suffered the loss of a portion of the face as a result of a cancer arising in the maxillary sinuses. The heroic cooperation of the subject and the ingenuity of those who fitted him with an artificial, transparent palate as well as other unusual devices enable the film to show the activities of these structures during the acts of mastication, swallowing, speaking and smoking.

Parts of the narration are not clear, particularly the reference to the supposed role of the frenum in limiting the rotation of the tongue and the reference to a "network" of glands. It is to be hoped that the authors will have an opportunity to make further photographs of this subject, who is making such a valuable contribution to medical science.

The film will be most informative and inspiring to medical students, especially in the course devoted to physiology of mastication and deglutition. For teaching purposes, it would be desirable to abbreviate the long section devoted to mastication and swallowing. It will also be important to otorhinolaryngologists and oral surgeons. Given a more systematic treatment of the subject of speech, the film could have been made more valuable to the specialist in the subject of speech rehabilitation. The teaching value of the film would have been enhanced by the addition of animated sequences of some of the action illustrated. The photography is excellent.

Human Beginnings. 16 mm., sound, color, 760 feet, showing time 21 minutes. Produced in 1950 by Eddie Albert Productions, Hollywood, Calif. Directed by Lester F. Beck, Department of Psychology, University of Oregon and photographed with children of the Walt Whitman School, New York City. Procurable on rental from Association Films, Inc., 35 West 45th Street, New York 19. For sale only to educational organizations under license.

The first half of the film portrays a class of 6 year old boys and girls discussing how they think a baby grows. The children illustrate their own ideas with simple clay models and drawings. Some of these reflect hostility and fear. After about 10 minutes of running time, there is a subtitled pause in the picture that would permit discussion of the classroom scenes already viewed by an audience of children or adults. In the second part of the film, one child tells about his baby sister and the story moves into this child's home. The mother and father explain about the new baby and how it will be born. Later the mother and new baby are shown at the hospital, with details of how the baby is cared for and how it nurses at the mother's breast. After the mother and baby come home, the social adjustment of the child to the baby is illustrated. The second half of the film is well done, effectively illustrating the well intentioned parents' efforts to properly brief the child about the birth of the baby, to bring about acceptance of the new arrival and later to develop a feeling of security for the older child through participation in the activities related to its care.

This film was reviewed by a group of health educators and a psychiatrist. Their reaction to the picture was totally different. Therefore, it was decided to publish both points of view.

The psychiatrist commented as follows: A generation ago, criticisms of this film would almost certainly have been raised on the grounds that, although it is expressly intended for showing to groups of all ages, the questions it explores should not be raised with "tender" or "impressionable" children. Today, fortunately, such strictures would trouble only those parents or teachers who have remained blind to the disturbing misconceptions and trepidations children develop when they are not properly instructed and prepared for this important event in their lives. The film has minor technical defects of voice recording in its early sequences, whereas its second section cannot, of course, explore all ramifications of the important parent-child interactions with which it deals. Nevertheless, the film is perhaps the best audiovisual medium to date for introducing the subject of children's attitudes toward childbirth for supervised classroom discussion, Parent-Teachers Association meetings or psychological study groups.

The health educators stated: Unfortunately there is serious question about the merit of the first part of the film. From a technical standpoint, the discussion of the children in its early phases is difficult to understand. While the material presented does demonstrate the innermost feelings of the children concerned, it not only points up misconceptions about birth but portrays feelings on the part of some of the children which border on the traumatic. Seeing the distorted attitudes in the first half of the film could be an unhealthy educational experience for children whose attitudes are wholesome and undeveloped. From this standpoint, it is not recommended as a film for young children. On the other hand, it is an excellent film for parents, child study and teacher education groups. The photography is excellent, however the direct recording in the classroom is poor.

CURRENT MEDICAL LITERATURE

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in Continental United States and Canada for a period of five days. Three journals may be borrowed at a time. Periodicals are available from 1939 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

20:801-900 (Sept.) 1950

Accurate Method for Glucose Determination. J. L. Pope.—p. 801.

Flame Photometer in Determination of Sodium and Potassium. E. C. Proehl and W. P. Nelson.—p. 806.

The Testes, Breast and Prostate of Men Who Die of Cirrhosis of Liver. H. S. Bennet, A. H. Baggenstoss and H. R. Butt.—p. 814.

Reaction to Accidentally Injected Rubber Plugs. T. B. Magath and J. T. McClellan.—p. 829.

Rapid Titrimetric Method for Determination of Blood-Sugar. F. Rappaport and E. Eichhorn.—p. 834.

Sternal Route in Measuring Blood Volume. C. Reich and L. Howard.—p. 837.

Effect of Folic Acid Antagonist, 4 Amino-Pteroylaspartic Acid, in Treatment of Polycythemia Rubra Vera. E. C. Bell and P. L. Davis.—p. 839.

*Persistent Truncus Arteriosus. Clinicopathologic Study. V. Moragues.—p. 842.

20:901-1000 (Oct.) 1950

The Van Den Bergh Reaction. N. W. Elton.—p. 901.

Clinical and Pathologic Effects of Space-Occupying Lesions of Bone Marrow. A. V. Pisciotta.—p. 915.

Multiple Myeloma: Lesions of Extra Osseous Hematopoietic System. J. Churg and A. J. Gordon.—p. 934.

Consideration of Phenomenon of "Sludged Blood" in Disease. R. H. Rigden.—p. 946.

Lesions Resembling Boeck's Sarcoid in Lymph Nodes Draining Area Containing Malignant Neoplasm. E. M. Nadel and L. V. Ackerman.—p. 952.

Comparative Study of Vaginal Smears and Cervical Cell Scrapings in Intra Epithelial Carcinomas. D. D. Kulcsar.—p. 958.

Electrophoretic Studies in Gaucher's Disease. A. R. Goldfarb, D. H. Atlas and P. Gaberman.—p. 963.

Persistent Truncus Arteriosus.—The truncus arteriosus, according to Moragues, is the most cephalic portion of the cardiac tube in the early embryologic development. The partitioning of the truncus into aorta and pulmonary trunk begins in the aortic sac. This division progresses through the truncus toward the ventricle. If this process is not completed, a partial type of truncus arteriosus communis persistens results. If there is no separation of the truncus, a complete type of truncus arteriosus communis persistens results, in which the pulmonary arteries arise directly and independently from the common arterial truncus, above the heart. The criteria for anatomic identification are that: (1) only one large arterial trunk be present at the base of the heart, (2) the arterial trunk must combine the features and functions of both the aorta and the pulmonary artery, on the one hand giving off the coronary and systemic arteries and on the other supplying blood to the lungs, (3) there is always an interventricular septal defect and (4) the trunk is usually in the position of the rider aorta. The author presents four cases of persistent truncus arteriosus with postmortem studies. Three instances were of the partial and one was of the complete type. Of the 37 instances of this malformation so far reported, 30 were in patients under one year of age. Patients with persistent truncus arteriosus usually have a systolic murmur and a thrill at the base of the heart, because of the ventricular septal defect. The pulse pressure may be high, and the clinical picture may simulate that of a persistent ductus arteriosus. The degree of cyanosis varies from case to case and frequently shows intermittent accentuation; it is greater when the subject is lying down. In roentgenologic examination, the anteroposterior plate usually shows enlargement of the cardiac outline, especially to the left. The pulmonary conus is absent, and the aortic knob may be prominent. Taussig claims that in persistent truncus arteriosus the cardiac outline in the left anterior oblique view is diagnostic, showing a sharp projection forward (shelf) of the upper border of the right ventricle. The author does not agree, since in two of his cases he did not find such a diagnostic silhouette. Besides, almost identical outlines have been seen in cases of tetralogy of Fallot.

Epidemic in Iceland Simulating Poliomyelitis.—Sigurdsson and his associates describe an epidemic that occurred in an Iceland community with about 7,000 inhabitants during the late fall and winter of 1948-1949. The first cases were given diagnoses of poliomyelitis. The epidemic reached its peak in the last week of November and lasted until the middle of February. The number of cases reported was 465, a case incidence of 6.7 per cent. Paresis was observed in 129 cases, but there were no deaths. The disease appeared to spread through personal contact, and cases were particularly frequent in the schools. The case incidence was highest by far in the age group of 15 to 19 years, was also high among adults, but was relatively low among children under 5 years of age. The disease was characterized by a low fever, which sometimes persisted for weeks, accompanied with a dull pain in one or more limbs, with or without such pain in the neck and back. Muscle tenderness, often confined to small areas, was also a prominent symptom. Paresis of one or more muscle groups, irregularly distributed, developed in about 28 per cent of the cases. The aches often persisted long after the disappearance of all objective symptoms. Sensibility disturbances were not infrequent, and complaints of nervous instability and irritability persisted for months in some cases. Symptoms of arthritis followed the infection in several instances. Four samples of feces were tested for poliomyelitis virus with negative results. Similarly, tests for the Coxsackie type of virus on baby mice were negative. Complement fixation tests of convalescent serums with antigens specific for several virus encephalitides also gave negative results. The fact that poliomyelitis virus or Coxsackie virus were not isolated in these cases does not exclude the possibility that one or both may have been present in the epidemic. It is possible that a strain of poliomyelitis virus with unusual pathogenic properties and of low virulence was responsible for this epidemic or that some unknown neurotropic virus was present.

Dosage Schedules of Penicillin.—Eagle and co-workers studied the factors governing the efficacy of penicillin given in different dosage schedules in a variety of experimental infections. Mice and rabbits were inoculated with Diplococcus pneumoniae types 1 and 3, group A and group B betahemolytic streptococci and Treponema pallidum. Results showed that the curative dosage of aqueous penicillin varies widely, as much *as a thousandfold, according to the schedule of its administration.* In a given infection, these widely disparate curative doses provide effective concentrations of penicillin for essentially the same aggregate period of time, modified only by the varying effects of the penicillin-free interval between injections. The common denominator of "penicillin time" is suggested as the primary determinant of its therapeutic activity. The rate at which bacteria die under the impact of penicillin in vivo is independent of its absolute concentration, provided only that the latter is in excess of the level which in vitro kills the particular organism at the maximal rate. Large doses of penicillin are more effective than smaller doses, primarily because of the longer time during which they provide that effective concentration. A penicillin-free interval between injections modifies the therapeutic activity of the drug in two respects. For a variable period of time after the penicillin has fallen to ineffective levels, the body may continue to dispose of bacteria damaged but not yet killed by the drug in some cases. The body thus contributes to the therapeutic action of the drug by reducing the time for which penicillin itself need act on the bacteria. Eventually, the organisms may recover from the toxic effects of the preceding injection and resume multiplication. An unduly long penicillin-free interval between injections therefore necessitates larger doses of penicillin and the provision of effective concentration for a longer aggregate time.

Aureomycin in Rickettsialpox.—Rose and co-workers treated five young adult patients and three children with proved rickettsialpox with aureomycin hydrochloride administered by mouth in doses of from 2 to 4 Gm. daily, with a total dose of from 2.25 to 16 Gm. No toxic side reactions were observed, other than occasional nausea, vomiting and diarrhea, which in one patient was sufficiently severe to require discontinuance of treatment. The temperature was restored to normal within 18 to 24 hours, with complete disappearance of headache and malaise in all patients. The acute febrile stage of rickettsialpox not treated with aureomycin usually lasts about one week, the fever and associated symptoms abating gradually over the final two or three days of the illness. Results of aureomycin therapy suggest that treatment with this antibiotic should be considered whenever the clinical diagnosis of rickettsialpox seems reasonably certain. No specific antibody response was detected by the complement fixation test in three of the eight patients during convalescence. It seems probable that aureomycin suppressed rickettsial multiplication so promptly and completely that the resulting antigenic stimulus was insufficient for detectable antibody production. Since the specific diagnosis of rickettsial disease is usually made in retrospect by serologic test with acute and convalescent phase serums, the use of aureomycin, which interferes with the immune response, may seriously affect the diagnosis by serologic methods and may even render it impossible.

Plasmacytosis and Hyperglobulinemia Due to Sulfadiazine.—Robertson reports two patients, one young woman with acute peritonitis following self-induced abortion and a boy aged 14 with bronchopneumonia, who were treated with sulfadiazine. Clinical and postmortem observations suggested probable hypersensitivity to sulfadiazine in both cases. The boy survived for more than five months after the onset of the symptoms, while the female patient survived for only 19 days. The lesions in both cases consisted of a widespread plasmacytosis, hepatitis and interstitial nephritis. The patient who survived longer had pronounced hyperglobulinemia during life, while serum globulins were increasing in the other patient at the time of death. The boy died of liver failure and the woman of kidney failure. In neither case was the diagnosis of hypersensitivity fully appreciated during life. The blood sulfonamide level of the woman on the day before death was 17.4 mg. per 100 cc., so that ample antigen was present even at this time to stimulate plasmacytosis and hyperglobulinemia as well as nephritis and hepatitis. The chief reason for consideration of plasmacytosis and hyperglobulinemia as a reaction to sulfadiazine in the boy rested on the large experimental evidence in animals that plasmacytosis and hyperglobulinemia are responses to a great variety of antigenic stimuli. Differentiation between plasma cell myeloma and massive plasmacytosis is difficult. A diagnosis of plasmacytosis should be considered when essentially normal cells of the plasmacytic series are observed in moderate numbers along with normal marrow elements in a patient exhibiting anemia and hyperglobulinemia. The author's two cases are the first in which sulfonamide compounds have been indicted as probably responsible for extensive plasmacytosis and hyperglobulinemia in addition to the lesions commonly seen in sulfonamide hypersensitivity.

Hazards in Radioactive Static Eliminators.—Silson points out that static electricity is generated in almost any operation where paper, plastic, rubber or some other dielectric is passed at high speed between rollers or other friction-creating surface. Static electricity not only interferes with production but may cause fire or explosions. Many physical means have been used in attempts to deal with the static charge. Probably the commonest is passage of the charged material over grounded metal tinsel or combs. Humidifiers, gas flames and high voltage electrodes have all been used, but each has disadvantages or hazards. The most recent of these methods is the use of radioactive alpha-emitting bars to ionize the air. Two types of bars have been advocated: one containing polonium, which is essentilly an alpha emitter, and the other containing radium which, in addition, gives off beta and gamma rays. The former, however, has had a somewhat limited field of usefulness. Radium bars consist of a mounting holding a thin strip of gold foil, which contains a measured quantity of radium. This is covered with several thin layers of plating. Two types of foil have been evaluated in operation, containing respectively 25 and 50 micrograms of radium per linear inch. The use of radium-containing bars requires control of the radiation hazards. Protection against gamma radiation involves the maintenance of a distance between the worker and the source, since shielding is generally impractical because of the great thickness of lead required. Beta radiation, on the other hand, requires a much greater distance but is much more rapidly controlled by shielding. Much of this shielding can be accomplished by the use of a properly designed housing for the source, without appreciable interference with the alpha radiation necessary for the ionization of the atmosphere. No additional precautions are necessary for protection against the alpha rays, except the use of gloves for momentary handling of the bars, as in cleaning them. There is no hazard from radon gas in a normally ventilated workroom and no appreciable adsorption of this gas in the dust and lint which collects on the bars. Care must be used in locating bars to provide proper distance and shielding for all phases of operation. Film badge monitoring and medical supervision of the workers are advisable as a final check on the adequacy of the control measures.

Penicillin and Bismuth Subsalicylate for Syphilis.—In the treatment of primary and secondary syphilis, Pardo-Castello and Pardo used a schedule of 20 doses of crystalline penicillin G. The drug was administered intramuscularly to 91 patients at the rate of 500,000 units daily dissolved in 3 cc. of isotonic sodium chloride solution. Twice a week, 10 to 20 doses of 0.13 Gm. of bismuth subsalicylate were given intramuscularly. All patients were clinically cured at the end of 60 days to two years. Of the 91 patients, 79 are still seronegatives; 11 are still seropositive with falling titer, and one patient returned with a serologic relapse and was retreated. The low rate of failure in this group suggests that penicillin in aqueous solution equals or surpasses penicillin in effectiveness in the several absorptive-delaying menstruums now in use. The authors believe that constant hemoconcentrations of penicillin are not necessary for the effective treatment of syphilis and that absorption-delaying menstruums are not essential. Larger amounts of penicillin administered during a longer time will prove more effective than the smaller quantities in a short time, as now advised in most schedules. The addition of bismuth subsalicylate to any schedule of treatment increases its therapeutic value.

Aureomycin Treatment of Syphilis.—According to Olansky and his collaborators, a study of the use of aureomycin in the treatment of syphilis was instituted in January 1949, at the Rapid Treatment Center, Callinger Municipal Hospital, Washington, D. C. This preliminary report is concerned with 108 patients. The four dosage schedules that were tried consisted first of 30 mg., 60 mg., 120 mg. or 240 mg. per kilogram of body weight per day. Since the disappearance time of organisms from the lesions was almost as short with the lower dosages as with the higher (23 to 30 hours) and since toxic reactions might be expected to be less severe and less frequent with lower doses, schedules of 30 and 60 mg. per kilogram daily were established for the remainder of the patients. The daily dose was divided into six portions and was administered at four-hour intervals. Aureomycin was found therapeutically active in syphilis. Better results were obtained with 60 mg. per kilogram per day for eight days than with the same or smaller doses for shorter periods of time. The two most important observations were that treponemas disappear from surface lesions at a slower rate and that the Jarisch-Herxheimer reaction is milder and less frequent after aureomycin than after penicillin administration. Aureomycin may therefore be most valuable in patients with late syphilis in whom a severe Jarisch-Herxheimer reaction should be avoided. It may also be valuable in the treatment of syphilis of the central nervous system or in cardiovascular syphilis. Allergic reactions to aureomycin were rare, therefore it should prove valuable in patients allergic to penicillin. Avitaminosis may occur either during or after the use of aureomycin. This fact and the high incidence of gastrointestinal symptoms (nausea, vomiting and diarrhea) that occur with aureomycin in the dosage necessary in syphilis constitute the disadvantages.

Aureomycin in Neurosyphilis.—Kierland and O'Leary treated 15 patients with neurosyphilis with orally administered aureomycin. Two patients did not tolerate the antibiotic because of severe gastrointestinal reactions, and one was transferred to a state institution after receiving only 8 Gm. of the drug. The remaining 12 patients were terated with aureomycin in doses of from 50 to 90 Gm. Three of the patients had asymptomatic neurosyphilis, two had meningovascular syphilis, one had tabes dorsalis, one had taboparesis and five had paresis. Aureomycin produces satisfactory clinical results. The majority of patients gained weight; there was an increased sense of well-being, and many minor subjective complaints disappeared. All but one patient with symptomatic neurosyphilis were clinically improved. The disease in the three patients with asymptomatic neurosyphilis showed no signs of progression. The spinal fluid of patients treated with aureomycin showed essentially the same response as that of patients treated with penicillin. The cerebrospinal fluid in 11 of the 12 patients showed steady and rapid diminution in the cell count and values for protein. The patient observed for the longest period achieved a completely normal cerebrospinal fluid. The early results suggest that aureomycin will produce the accumulative and long-standing beneficial results achieved by penicillin alone or penicillin plus fever therapy. The dosage of aureomycin used has varied considerably, but approximately 60 Gm., given in doses of 2 to 4 Gm. daily, seems sufficient for a single or first course of therapy. Reactions involving the gastrointestinal system appeared in approximately 50 per cent of the cases. A reduction of the daily doses often permitted continuation of medication. Aureomycin is indicated for patients with neurosyphilis who have a resistance or hypersensitivity to penicillin.

Oral and Pharyngeal Complications of Chloramphenicol Therapy.—Williams directs attention to the oral and pharyngeal complications that arise during the treatment of infections with chloramphenicol. Of 200 patients receiving chloramphenicol, glossitis and black tongue, stomatitis, pharyngitis and infection of the mouth and throat developed in 12 (6 per cent) while they were being treated with the drug The symptoms in six of these patients were so severe that therapy had to be discontinued The patients in whom the oral and pharyngeal complications developed either were of the older age group or had chronic disease Five of the 12 had long-standing gastrointestinal disease The oral or pharyngeal reactions were most severe in those patients who received other antibiotics in addition to chloramphenicol Invasion by a yeastlike fungus, Monilia (Candida) albicans, occurred in nine patients after the bacterial flora had been suppressed by chloramphenicol Administration of supplementary vitamins failed to prevent the development of oral and pharyngeal reactions in three patients with ulcerative colitis Supplementary vitamins were not given to the remainder of the group with oral complications

Effects of Dibenamine® on Hypertension—Wunsch and his associates studied the effect of N,N dibenzyl-β chlorethylamine (dibenamine®) on 31 patients with severe hypertension The drug was administered by slow intravenous drip (45 to 60 min), in doses of 2 to 10 mg per kilogram of body weight to 14 patients, including 10 in the malignant phase of hypertension Enteric coated tablets of dibenamine® were given orally to 17 patients in doses of 0 25 to 0 5 gm, one to three times daily Toxic reactions were experienced by all alert patients Results of the study showed that given by the intravenous route, this drug is of value in the symptomatic relief of hypertensive encephalopathy, that it is merely an accessory measure to combat an acute episode of hypertensive encephalopathy in the hope that sufficient improvement may be obtained to permit sympathectomy and that because of its toxicity it should be reserved for patients failing to improve on standard medical measures Dibenamine® given orally was not tolerated in therapeutically effective doses All doses should be given by slow intravenous infusion over a period of at least one hour, to reduce the danger of severe toxicity The initial dose should be limited to 2 to 3 mg per kilogram and, if tolerated, subsequent doses should be increased to the therapeutic range of 5 to 10 mg per kilogram Intravenously administered dibenamine is contraindicated in the treatment of the ambulatory hypertensive patient, not only because of its toxicity but also because of the pronounced and prolonged orthostatic hypotension it causes

Precordial Electrocardiograms Derived from V and CF Leads—Kistin and Brill report seven cases in which there were clinically significant differences between precordial electrocardiograms recorded in succession, once with the Wilson distant electrode (V leads) and once with the distant electrode on the left leg (CF leads), the precordial electrode remaining in place. Abnormalities occurred in the CF leads, the T waves were inverted in all cases, and in two cases, there were abnormal Q waves, whereas the corresponding V leads were normal There was no definite evidence of heart disease in any of the cases, although there were questionable symptoms or signs in some It was concluded that the CF leads gave false indications of cardiac disease, while the normal V leads were more consistent with the cardiac status The discrepancies were due to high potentials at the left leg compared to the potentials at the precordium and at the Wilson electrode Such potentials may occur in the absence of heart disease and may be related to alterations in the position of the heart and its relation to adjacent structures

Liver Injury and Repair.—Ravdin and Vars believe that the reduction in functional capacity of the liver, which at times occurs following anesthesia and operation, is due in large part to anoxia Failure of an adequate oxygen supply is the chief cause of this anoxia during anesthesia During an operation anoxia may result from any condition that impedes blood flow to the liver, even when the circulating blood is well oxygenated, or from a reduced blood flow, as in shock In a patient with suspected acute or chronic liver injury, the prevention of hepatic anoxia during and after operation is of major importance to recovery A diet adequate in total calories and in composition will partially protect the liver from a wide variety of noxious agents and will facilitate repair of the liver damaged by these agents It will even facilitate repair in the presence of recurrent cholangiohepatitis The importance of an adequate intake of protein and of an optimal number of calories in the preoperative period, therefore, takes on a new significance, for repair can be begun and functional capacity improved before the patient is subjected to the assault of anesthesia and operation

Postoperative Salt Retention and Adrenal Cortical Function.—Johnson and his collaborators direct attention to the temporary disturbances in the electrolyte and protein metabolism that occur in the period immediately following a major surgical operation. They used the electrolyte concentrations of serially obtained samples of sweat as an index of changes in the activity of salt-active adrenal steroids Sweat tests and eosinophil counts were made of 12 men and two women before and after such operations as gastric resection, cholecystectomy, herniorrhaphy, splenectomy, closure of colostomy and varicose vein ligation. All subjects were in good nutritional state, and most received at least 5 Gm. of sodium chloride per day orally or parenterally during the postoperative period. The results of the sweat analyses are shown in diagrams. Activities of three main types of adrenocorticosteroids, namely, electroyle-regulating 11-desoxycorticosterone-like steroids, 11-oxysteroids and steroids having activities and end products characteristic of sex hormones are discussed. A major surgical procedure constitutes an "alarming stimulus" resulting in increased production of pituitary adrenocorticotropic hormone with a resultant increase of adrenal cortical activity during the first five to nine days after operation. Studies of the changes in the composition of thermal sweat before operation and periodically after operation indicate that in the immediate postoperative period there is increased activity of those adrenal steroids that cause retention of sodium, chloride and water. It is concluded that increased production by the adrenals of desoxycorticosterone-like steroids accounts, at least in part, for salt retention and the accompanying potassium diuresis after operation.

Effect of Visammin on Coronary Artery Insufficiency.—According to Best and Coe, visammin (khellin) is a crystalline substance isolated from the seeds of the plant Ammi visnaga, which grows abundantly in the eastern Mediterranean region and which has been used for centuries in the treatment of conditions characterized by spasm of smooth musculature. The authors report on nine patients with a history of angina pectoris on exertion, for coronary insufficiency as shown by electrocardiogram, but with no evidence of congestive heart failure, hyperthyroidism or anemia and no recent myocardial infarction. The effectiveness of visammin in the treatment of these patients was evaluated electrocardiographically by means of the exercise tolerance test, the anoxemia and the ergonovine test. Coronary insufficiency was shown in results of 14 electrocardiographic tests of nine patients. Results of 10 of these tests reverted to normal with visammin therapy. This beneficial effect was not noted with placebo therapy. Eight of the nine patients noticed an increase in exercise tolerance and a decrease in number and severity of anginal attacks. Nausea and vomiting of moderate severity occurred in three patients during the visammin therapy. Visammin appears to be of value in the treatment of angina pectoris.

Reflexes Modifying Circulation.—Peterson says that during the last several years records have been obtained of intra-arterial pressures in nearly 1,000 persons by direct intra-arterial catheterization and electrocardiography. The records were obtained during anesthesia, operation, clinical disease and physiological and pharmacologic experiments. The records demonstrate the occurrence in man of cardiovascular reflex responses that are not generally recognized and are not explainable by existing concepts of reflex effect. The stimulation or alteration of certain reflex areas produces an apparent primary weakening of ventricular contraction (in some cases concurrent with the induction of bradycardia and in others independent of changes in the pacemaker system of the heart) in addition to alterations in stroke volume, cardiac filling and arterial pressure. These changes follow modifications of the reflex systems that are said to mediate their activity on the heart through the vagus nerves. In addition, the effects are not consistent with the presently accepted response of the sympathetic nervous system. These reflexes modify the manifestation of Starling's law. Spinal anesthesia to a sensory level of the twelfth thoracic segment had abolished the classic response of the pulse rate following changes in stroke volume, cardiac filling and arterial pressure. From this evidence it was concluded either that there are certain fibers from the vagus nerves that enter the ventricles directly and produce an effect of weakened strength of contraction or that sympathetic inhibition occurs far more rapidly and quantitatively in man than has been previously supposed.

Isolation of Hypertensin from Blood of Dogs in Artificial Kidney.—With the aid of the artificial kidney, Kahn and his associates dialyzed out of the circulating blood of animals a vasopressure substance. This substance was recovered from normotensive and hypotensive dogs and from animals with malignant hypertension. The method for concentration of this substance in the dialysate is described. The substance conforms to all the tests for the identification of hypertensin. Intravenous injections of 0 25 to 0 50 cc of it produce an immediate steep rise in blood pressure, the maximum rise occurring in one minute or less and the return to normal in three minutes or less The pressor effect of intravenous injections of the dialysate was unaffected by previous injections of cocaine, atropine or piperoxan (benzodioxan 933 F) but was potentiated by a previous injection of tetraethylammonium chloride. The pressor material was found to be water and alcohol soluble and ether insoluble and slowly dialyzable. In the dialysates in which there was a sufficient amount of the pressor material, this substance was found to be destroyed by trypsin, hyptertensinase and by boiling at p_H 12 but not at p_H 1.

Dietary Treatment of Hypertension.—Dole and his associates report on six patients with hypertension treated by the rice-fruit diet of Kempner. The patients remained in continuous residence in a metabolic ward while observations were made on the evolution of clinical and metabolic changes. Five patients showed improvement as evidenced by a significant reduction in mean blood pressure, decrease in heart size, improvement in fundi and return to normal of low or inverted electrocardiographic T waves Restriction of sodium, but not of chloride, appeared to be necessary to obtain the clinical effect. An investigation was made of the sufficiency of the diet for maintenance, as shown by the attainment of steady weight, balance with respect to nitrogen, sodium, potassium and chloride and normal serum electrolyte concentrations. The five patients with normal renal function appeared to reach the equilibrium on this diet or to approach it closely. The sixth, who had impaired kidneys, achieved the first two of the criteria but probably became slowly depleted of body sodium, despite apparent balance, since her serum concentrations were reduced. With the added burden of ammonium chloride administration, she developed severe dehydration and acidosis. Adaptation proceeded slowly in all. Three months were required for attainment of steady weight by the smallest person and a little more than five months were required by the largest. Since the clinical benefit of the diet did not appear to be associated with depletion but, on the contrary, with successful adaptation, it was suggested that the therapeutic effect is a consequence of the steady adaptive response to limitation of sodium intake. Whether the high incidence of clinical improvement was due to the selection of relatively young persons with uncomplicated hypertension or whether it was due to the detailed supervision of dietary intake or even whether the sheltered environment of a metabolic ward may have contributed to the favorable effect was not investigated. These considerations, although pertinent to the general problem of dietary treatment, are not directly relevant to the association between clinical and metabolic change.

Life Stress and Renal Circulation.—Pfeiffer and his associates studied renal hemodynamics and blood pressure variations in 35 patients. Elevation in both systolic and diastolic blood pressures was induced by discussion of important personal topics having a threatening significance in 13 patients with normal blood pressure and in 22 with hypertension. During the emotionally induced rises in blood pressure, there was a constant fall in effective renal blood flow and a rise in filtration fraction, indicating an increase in the resistance offered by the renal arterioles. The changes in renal blood flow, filtration fraction and vascular resistance were similar in direction in both the hypertensive and normotensive groups, but there was an indication that the decrease in the renal blood flow and filtration fraction was more significant in the hypertensive group. The increase in renal vascular resistance was unequivocally greater in the hypertensive group. Following lumbodorsal sympathectomy and splanchnicectomy, induced elevations in systemic arterial pressure were accompanied with a reversal of the above pattern, i. e., a fall in filtration fraction and a less intense renal vascular constriction. This is interpreted as a failure, in whole or part, of the efferent glomerular arteriole to participate, although the afferent arteriole is still responsive. The concept is advanced that the kidney, under usual conditions, has two more or less independent vascular mechanisms: (*a*) a sympathetic control of the efferent glomerule arteriole and (*b*) an intrinsic or intrarenal humoral control of the afferent glomerular arteriole, possibly involving the juxtaglomerular myoarterial apparatus.

Pulmonary Paraffinoma (Lipid Pneumonia).—Berg and Burford discuss pulmonary paraffinoma or advanced lipid pneumonia. In the infantile type of lipid pneumonia, alveoli contain oil-filled macrophages and free oil globules. The lesion is usually more extensive than the adult type and is unaccompanied with the late changes of fibrosis and granuloma formation. The adult type of lesion occurs in persons who are habitual users of mineral oil orally, intranasally or intratracheally. Neurogenic and mechanical interference to swallowing may be a factor but is by no means always present. Mineral oil is the causative agent. There may be no pulmonary symptoms or there may be chronic cough with or without sputum, hemoptysis, low-grade fever, frequent lower respiratory infections and dyspnea on exertion. The minimal symptoms presented by the patient are in striking contrast to the gross roentgenologic findings. The authors cite histories of six patients with pulmonary paraffinoma. Clinically, radiographically, at operation and even in frozen section the lesion is often confused with carcinoma. Roentgenologic examination usually reevals circumscribed tumor-like shadows without hilar adenopathy and with peribronchial infiltration, especially in the lower lobes. At operation the lesion may so mimic carcinoma as to result in needless pneumonectomy when lobectomy would have sufficed. The pathological picture of the early type of lipid pneumonia in adults resembles the gray hepatization stage of lobar pneumonia. The paraffinoma consists of one or a group of nodular masses of varying size lying in close proximity to major bronchial trunks. The mass is firm, and the cut surface is mottled yellow to grayish-yellow. Small cavities filled with oil are seen, and the entire cut surface is oily. When this histologic picture is found and when mineral oil is demonstrated by positive staining with Sudan red and by absence of staining with osmic acid, the lesion can be diagnosed as a paraffinoma.

Surgical Treatment in Pulmonary Coccidioidomycosis.—Cotton and Birsner present observations on 30 patients with pulmonary coccidioidomycosis whom they subjected to surgical treatment. The diagnosis was confirmed in all instances by one or more of the following laboratory signs and methods: spherules in sputum, complement-fixation test, culture, guinea pig inoculation and/or pathological specimen. Twenty-seven of the patients were operated on for cavities and the others for empyema. The following types of operations were done: pneumonectomy in five, lobectomy in 11, segmental lobectomy in eight, wedge resection with decortication in five and decortication plus thoracoplasty in one. Surgical treatment may prevent death and is effective in arresting the disease process. It does not cause dissemination of the disease to the skeletal or nervous system but may prevent dissemination. It is indicated in pulmonary coccidioidomycosis when cavities are of giant size, when the lesions are secondarily infected or blocked or when they have ruptured and caused spontaneous pneumothorax or empyema. Other indications for surgical treatment are nonexpansile lung, hemoptysis, "coccidioma" and failure of medical treatment. Such measures as bed rest, crushing of phrenic nerve, pneumothorax and pneumoperitoneum gave unsatisfactory results. Postsurgical examination of the specimens revealed two causes for the failure of collapse therapy: (1) the cavity, although appearing thin-walled roentgenographically, actually had a dense fibrinous wall; and (2) dense adhesions were present from the cavity wall to the thoracic cage. Lung complications resulting from pulmonary coccidioidomycosis should be evaluated surgically from the standpoint of pathological lesions, without regard to the fungus origin of the disease. Pulmonary cavities due to tuberculosis and coccidioidomycosis do not constitute a contraindication to surgical management.

Histoplasmosis in Infants.—According to Kotcher and Leikin, histoplasmin sensitivity surveys indicate that Kentucky is in a highly endemic area. They report on seven infants, all of whom were less than 8 months old. The duration of symptoms previous to admission was from two to seven weeks, with an average of 4.3 weeks. The symptoms were fever, irritability, abnormal distention because of hepatosplenomegaly, diarrhea, yellow urine and lethargy. Six of the infants showed signs of upper respiratory infection. All had hepatosplenomegaly. Only one had lymphadenopathy. Six sets of skin tests were done on the parents. Five sets showed both parents to be positive reactors. In the other set the father was positive. Histoplasmin skin tests were done also on four of the patients. The results were negative in one and equivocal in another. Of the other two, one gave a positive reaction on initial examination and the reaction of the other became positive one month after being negative. Histoplasma capsulatum was recovered from the bone marrow in six patients, either on smear or culture or both. The blood revealed the organisms in five patients. The organisms were seen on microscopic examination of the splenic pulp of the patient who had a splenectomy. Roentgen examination of the chest revealed that three patients had infiltration in the lungs, mainly in the hilar regions. All patients were given supportive treatment, including blood transfusions, vitamins and parenteral fluids. All patients received penicillin. A sulfonamide was given to four and aureomycin to two infants. No remedial effect could be ascribed to penicillin or sulfonamide. One of the patients who received aureomycin seemed to improve temporarily. Five patients are known to have died. One patient, who was transferred to Vanderbilt Hospital for further treatment, was known to be living eight months after the onset of symptoms. The eighth patient was taken out of the hospital against the advice of physicians. Anemia, leukopenia, fever and hepatosplenomegaly were the most frequent symptoms. A definite diagnosis can be made on the basis of direct demonstration of the fungus by microscopic examination of stained bone marrow, peripheral blood and tissue impressions of material obtained by biopsy. These materials should also be cultured to recover the tuberculate chlamydospores characteristic of Histoplasma capsulatum.

Cause of Certain Types of Tinnitus.—The Fowlers observed that people who have deafness associated with severe tinnitus are usually highly sensitive, tense or nervous. In their experience, sudden deafness and tinnitus occur frequently with severe liver disturbances, with duodenal ulcer and ulcerative colitis. They believe that psychic and neurovascular factors play a part in this combination of symptoms. Formation of "sludges," which are agglutinated masses of erythrocytes, represent one factor. Sludges follow trauma, infectious or toxic diseases. Even a provocative remark may cause a concentration of the smaller vessels, which is often followed by sludging of the blood. The authors studied sludging and found that vessel contraction, sludging and the accompanying phenomena can affect not only the neural elements in the ear but also nonneural tissues. They did not demonstrate incontrovertibly that emotionally induced blood sludge produces tinnitus and deafness, but they feel that there is strong evidence that this may be the case in some patients.

Rupture of Interventricular Septum.—Nareff and his associates describe four cases in which interventricular septal defects developed in the course of myocardial infarction. In three of these cases the septal rupture was recognized before death and was corroborated at necropsy. Rupture through the septum often results in a speedy death, although not as quickly as in nonseptal rupture of the myocardium. Perforation of the interventricular septum is usually preceded by a dramatic deterioration in the condition of the patient, although the time of the rupture may not be noticed. There may be pain, and there is usually peripheral circulatory failure and the rather abrupt appearance of, or increase in, the signs of failure of the right side of the heart. There is often associated nausea, vomiting and abdominal tenderness. Cyanosis, dyspnea and tachycardia may suggest pulmonary embolism. When the communication is small, there may be little effect on the cardiovascular dynamics. The most striking clinical feature is the appearance of a typical murmur, which is often loud and harsh. It is systolic in time, is often accompanied by a thrill and is usually located to the left of the lower end of the sternum. The diagnosis of interventricular septal rupture following myocardial infarction can be made when this condition is suggested by the clinical or electrocardiographic findings, or both, or when the presence of the typical harsh systolic murmur over the lower precordium associated with shock and often with *right-sided heart failure is noted.*

Clinical Study of Toxoids with Aluminum Phosphate.—McComb and Trafton point out that immunizations combining diphtheria and tetanus toxoids with pertussis vaccine formerly had alum or aluminum hydroxide as adjuvants. He reports on the use of a new product in which aluminum phosphate was used as an adjuvant to tetanus toxoid. The diphtheria and tetanus components were purified and concentrated by ammonium sulfate fractionation. The pertussis vaccine was prepared from phase 1 organisms grown on Cohen-Wheeler fluid medium and standardized at 20,000,000,000 organisms per cubic centimeter. This material was furnished to physicians, clinics and institutions who agreed to report the reactions. Efforts were made to obtain bloods one month after the last injection. The antigen was injected intramuscularly in three 0.5 cc. doses four weeks apart. The reactions following these injections as well as 134 "booster" doses were not severe either locally or generally in this group of children. The immunity response to the tetanus component was more than adequate one month after the last dose in all the children tested. As there were no previous tetanus immunizations in these children, the tetanus immunity as shown by postinjection titers should be an accurate index of the immunizing ability of this antigen. Adequate immunity was found in all the bloods tested for diphtheria antitoxin and in 75 per cent of those tested for pertussis immunity as indicated by the agglutination tests. The limitations in interpretation of these two tests are pointed out.

Myasthenia Gravis and Thymoma.—According to Derow and his associates, thymoma occurring in about one sixth of patients with myasthenia gravis is usually encapsulated, grows slowly and is generally regarded as a benign neoplasm. Ten per cent or less of these tumors extend by continuity into the adjacent pleura, lungs, pericardium or the superior vena cava. Separate, discrete, secondary deposits of thymomas, occasionally found at a distance on the pleura, have been interpreted as implants and not as true metastases. Metastases of this nature from thymomas in other organs have not been reported. None of the reported highly malignant, widely metastasizing tumors arising from the thymus have been associated with the symptoms of myasthenia gravis. The authors report a patient with typical symptoms of myasthenia gravis. During the first two and a half years of her five year illness, there was dysphagia and dysarthria related to fatigue, emotional upset or respiratory infection. Five years before her death a mediastinal mass was discovered on roentgen examination and was treated by radiation. The myasthenic symptoms were severer during the last two and a half years, and required oral administration of neostigmine (prostigmine®) bromide. Repeated roentgen examination revealed a mediastinal shadow, interpreted as a tumor at the onset of the illness. There were temporary changes in its size after roentgen irradiation, extension to the apex of the left lung prior to exploratory operation and, shortly before death, the appearance of two new shadows suggestive of metastases in the right lung. Operation and autopsy revealed that one of the shadows in the right lung was a pulmonary infarct. The irradiation did not prevent the spread of the mediastinal tumor and did not improve the myasthenic symptoms. A search of the literature failed to reveal a similar case.

Genital Smears in Diagnosis of Adenocarcinoma.—According to Cuyler and his associates, smear preparations are far less accurate in the diagnosis of adenocarcinoma of the *uterus than in the* detection of squamous cell cervical cancer. Their technic of making and staining the smears was that of Papanicolaou and Traut, with slight modifications. An attempt was made to obtain smears on all new patients who came to the obstetric and gynecologic clinics and on all return patients over 30 years of age. Both vaginal and cervical smears were made. During the period 1947-1949, 33,655 genital smears from 10,029 women were studied. According to pathological studies, 434 of these patients had cancers involving the genital tract. In 384 patients the lesion was primary in the uterus. Squamous cell carcinoma of the cervix comprised 83.3 per cent of these lesions or 320 patients. Adenocarcinoma of the uterus was found in 16.4 per cent or 63 patients. Forty-six patients (11.9 per cent) had adenocarcinoma of the endometrium, and 17 patients (3.9 per cent) had adenocarcinoma of the endocervix or of the cervical stump. There was one adenoacanthoma of the uterus. The percentage of false negative diagnoses for adenocarcinoma of the uterus was 15.9, as compared to 8.4 for squamous cell cervical cancer. Histocytological similarities between hyperplastic endometrium and malignant endometrial lesions may account for errors in interpretation. Metaplasia may be responsible for the confusion of adenocarcinoma of the uterus with squamous cell carcinoma of the cervix. Faulty smears—those composed principally of blood and debris—account for a significant percentage of false negative diagnoses. It is suggested that more effort be made to establish criteria for the recognition of early adenocarcinomas and that the investigators in the field of smear cytology be not content to accept as insurmountable the difficulties of this method of detecting adenocarcinoma.

Transplantation of Parathyroid Gland.—Bland and his associates report a woman aged 40 who had been subject to sporadic tetanic seizures since 1943. She had had a subtotal thyroidectomy in 1941, with relief of symptoms for 18 months. She was subjected in 1943 to further removal of the thyroid tissue for the relief of recurrent hyperthyroidism. She occasionally had a drawing and numb feeling in her hands after the last operation. She was readmitted six weeks later with a complaint of carpopedal spasm and a feeling of drawing in her abdominal wall, feet and legs. Her blood calcium was 5.4 mg. per 100 cc. She was given calcium wafers and vitamin D. During the next five years the patient had tetanic seizures at intervals varying from a few hours to six weeks. She was readmitted to the hospital for regulatory treatment on four occasions. Her teeth had been crumbling and would not hold fillings. Transplantation of parathyroid tissue was advocated. Thyroid and parathyroids were removed from the body of a 29 year old man, who had died on arrival at the hospital. Eight bits of tissue thought to be parathyroid were excised and placed in sterile saline solution at a temperature of 99 F. The woman with hypoparathyroidism had meanwhile been prepared for operation. Eight small beds were formed in the body of the rectus muscle of the woman by blunt dissection, and one bit of parathyroid tissue was placed in each. The postoperative course was uneventful. The patient returned for follow-up examinations nine times during the subsequent four months. She occasionally felt nervous and jittery, and on one occasion felt a drawing sensation in her hands. There was no evidence of hypocalcemia. She continued to take 1 grain (60 mg.) of thyroid extract twice a day. Her appetite was good, and when last seen she was working a full eight hour day without difficulty. The patient appears to have been cured.

Tularemia from Rural Water Supply.—Jellison and his co-workers point out that contamination of natural waters in Montana with Pasteurella tularensis has been reported by a number of investigators. Since 1942, repeated contamination of numerous streams, often persisting for months, has been demonstrated at the Rocky Mountain Laboratory. In most instances, the presence of the organism in water has been associated with the occurrence of tularemia in beavers and muskrats inhabiting the streams or ponds concerned. Many cases of tularemia have been contracted by persons who skinned or handled such diseased animals, but there has been little evidence of human infection resulting from direct contact with contaminated water. The occurrence in Gallatin County, Mont., of four cases of tularemia associated with one domestic water supply is the subject of the present report.

Irradiation Therapy in Neoplasms of Brain.—Peirce and Bouchard treated with irradiation 243 patients with malignant tumors of the brain and stem. Glioblastoma multiforme, astrocytoma and the unclassifiable malignant gliomas comprised two thirds of the malignant neoplasms of the brain and brain stem. There were 13 instances of fibroblastoma and 32 of pituitary adenoma. Close cooperation between neurosurgeon and radiologist is imperative. Personal daily attention by the radiologist, with treatment according to the clinical status of the patient, is mandatory. The initial daily doses should be relatively small (100 r) and should be given preferably through one port. If no untoward reaction ensues, the daily dose and number of ports may be gradually increased, so that by the tenth day it will usually be possible to administer 150 to 200 r through each of two ports per day, with irradiation of a half-value layer 2 mm. Cu. The survival of patients with glioblastoma multiforme after operation and irradiation was 12 months or more in 47.9 per cent, 15 months or more in 29.1 per cent, 20 months or more in 22.9 per cent and 30 months or more in 8.3 per cent. A minimum tumor dose greater than 7500 r will be required to obtain further improvement. The survival of patients with astrocytoma after operation and irradiation was 12 months or more in 87.8 per cent, 24 months or more in 56.1 per cent, 36 months or more in 43.9 per cent, 48 months or more in 34 per cent, 72 months or more in 24.3 per cent and 96 months or more in 9.7 per cent. A minimum tumor dose of about 9,000 r may afford an additional period of useful life to an increasing number of these patients. The unclassified malignant gliomas appeared to fall in between the two previous types as to degree of malignancy and susceptibility to irradiation. In spite of the malignant character of these neoplasms, irradiation therapy has lengthened survival time and, in not a few cases, useful life. Conservative optimism is still warranted.

Fluorescein in Diagnosis of Brain Tumors.—According to Moore and co-workers, differences between normal and neoplastic brain tissues are accentuated with the use of sodium fluorescein, thus affording the neurosurgeon a better chance of diagnosing and localizing brain tumors. Sodium fluorescein is also of value in studying non-neoplastic lesions of the central nervous system. Attempts to render brain tumors radiopaque by the selective retention of radiopaque compounds were unsuccessful. The use of radioactive diiodofluorescein for the diagnosis and localization of brain tumors proved feasible. Clinical studies revealed inherent weakness in the method, such as the size of tumor that could be detected (tumors less than 3 cm. in diameter were often missed) and the failure of certain tumors to retain a sufficient quantity of dye to make their detection practicable. Detector geometry and shielding proved to be factors in the ultimate accuracy of the analysis as well as in the localization of brain tumors. Studies of the excretion of radioactive diiodofluorescein revealed that most of the dye is excreted in the bile and can be recovered from the feces. In patients with biliary obstruction the dye is excreted wholly in the urine. There is little danger of radioactive iodine (I^{131}) splitting off from radioactive diiodofluorescein.

- Corticodiencephalic Gastrointestinal Syndromes in Epileptics (Part IX). T. S. P. Fitch, A. W. Pigott and S. M. Weingrow.—p. 817.

Ulcerative Colitis.—Lahey reports on 750 patients with ulcerative colitis. Most of these patients were treated medically, and 327 were followed from five to 15 years. Either definite improvement or complete relief was brought about by medical management in two thirds of those with milder forms and in one third of those with the severer forms of the disease. Emergencies arise that cannot be handled medically. Ileostomy can now be done with complete satisfaction. Comparison of mortality in two groups of patients, one of 145 in whom ileostomies were done early in the history of surgical management of ulcerative colitis and one later group of 70, showed a prohibitive mortality of 22.3 per cent in the first group and a mortality under 4 per cent in the second group. The lower mortality in the second group is due to the fact that surgical intervention was not performed on dying patients. Resection of the colon should not be delayed until joint changes occur. Ileostomy should be done before severe intoxication develops. Colectomy should be performed before too much blood is lost by hemorrhage. There is growing evidence that patients with ulcerative colitis from whom the colon is not removed have an increasing percentage of carcinomas. The patient who has undergone ileostomy can live with complete comfort and participate in every activity. Modern ileostomy bags are flat and are so made that they fit accurately, with no skin exposed. There is no skin irritation, and the area need not be skin-grafted.

Surgical Treatment of Duodenal Ulcer.—Crile treated over 400 patients with duodenal ulcers by vagotomy. The first 100 of these patients have now been followed for from one to two years. Bilateral vagotomy plus gastroenterostomy was done in 73 and pyloroplasty in 27 of this group. There was little difference in the end results in these two groups. One patient died in the hospital after the operation. One patient died of unrelated causes six months after the operation. Three patients could not be located within the first year. Of the remaining 59 patients, 35 had transitory or occasional diarrhea and 15 had mild transitory vomiting. Three patients had recurrence of their ulcer-like pain. No appreciable symptoms occured in 82 patients, 10 patients were improved and therapy failed in three. Results obtained in a series of 87 patients treated by vagotomy with gastroenterostomy or pyloroplasty were compared with those obtained in a group of 87 patients treated by gastric resection or gastroenterostomy in the years immediately preceding the advent of vagotomy. The severity of the disease was exactly the same in both groups. Four patients with vagotomy had ulcer-like pain as compared to 16 of the gastric resection groups. The incidence of persistent symptoms of ulcer thus was four times as high in the gastric resection group, and most of these patients were continuing some form of dietary management to control it. One jejunal ulcer developed over a period of three years in the vagotomy group and three in the gastric resection group. Four hemorrhages occurred after gastric resection or gastroenterostomy, and there were no hemorrhages in the other group. No death occurred in 257 consecutive vagatomies with gastroenterostomy or pyloroplasty. This operation, therefore, is relatively safe. It should be reserved for patients with complicated duodenal ulcers. A posterior gastroenterostomy should be performed at the most dependent aspect of the greater curvature to drain the denervated stomach.

Clinical Usefulness of Estrogenic Hormones.—Page bases his evaluation of the use of estrogens on personal experience and on the opinions expressed by many medical associates. He discusses routes of administration, choice of preparations, dosage and the physiological actions of estrogens. He admits that his conclusions as to the usefulness of the hormones might be regarded as rather arbitrary, since it is doubtful whether any two physicians would independently arrive at the same conclusions. Nevertheless, he feels that it might stimulate thoughtful discussion to offer a tentative classification of the usefulness of estrogens in practice. For four groups of disorders, estrogens are classified as follows: (1) of proven usefulness, (2) possibly useful or suitable for adjunctive therapy, (3) doubtful indications and (4) of experimental value (judgment reserved). Before estrogen treatment is instituted the following questions should be answered: 1. Is there an indication for an estrogen? 2. Is there a demonstrable deficiency, or is the hormone to be used to inhibit pituitary function, to neutralize an androgenic effect or to utilize its anabolic effect on the skeletal system? 3. Is this the minimal dosage necessary to accomplish the objective, and is the timing correct? 4. Have carcinoma, endometriosis, myomas, a fibroadenoma of the breast or other organic lesions that might be stimulated unfavorably by estrogens been ruled out? 5. Could harmful effects result? Will the treatment produce withdrawal bleeding in a postmenopausal woman, thus substituting a diagnostic problem for a simple therapeutic one? May it interfere with a normal menstrual cycle in such a way as to defeat the objective? Has the patient been prepared for the possible effects of estrogen? 6. Does the severity of the symptoms justify the means? Is this the most economical preparation suitable for the purpose and the most sensible route of administration?

Surgical Treatment of Ulcerative Colitis.—Sullivan believes that many patients with ulcerative colitis require surgical treatment. The time-honored treatment of ileostomy followed by colectomy controls the disease, but this treatment requires two major operations and meticulous attention to detail. Furthermore, few cases have been reported in which bowel continuity was reestablished by ileoproctostomy, because operation was not performed until irreversible changes had been produced. The author performed vagotomy in seven patients with ulcerative colitis and found that this operation was followed by immediate and dramatic improvement in six and slower improvement in one. This new surgical approach to the treatment of ulcerative colitis offers possibilities, and further trial is indicated.

Arsenic Content of Tobacco.—Daff and Kennaway investigated the arsenic content of 15 brands of cigarets and found that the amounts present varied from none to 106 micrograms of arsenic trioxide per gram of tobacco. The concentration of arsenic in cigarets containing the larger amounts varied greatly. This irregularity is probably due to the method by which the arsenic could have been introduced, namely, by the spraying of the plants with insecticides. If the arsenic were absorbed by the roots, one might expect a more uniform distribution. In some areas, only the seedlings are sprayed, and presumably this arsenic is lost in the course of transplantation and further growth. The authors are obtaining data on the use of arsenical solutions in the areas where the tobaccos examined are grown. Of the arsenic volatilized in smoking, a part must escape while the cigaret is not in the smoker's mouth, and a part of what he inspires is expired again, hence the amount retained must be small.

Tumor Production in Thyroid.—Doniach attempted to determine whether radioactive iodine (I^{131}) is carcinogenic to the thyroid gland of the rat. This seemed likely, since radioactive iodine is specifically concentrated in the thyroid, whose cells are thereby submitted to a course of beta ray irradiation. The problem is important, since this iodine is being used in clinical medicine, in both tracer and therapeutic doses. Hyperplasia and adenomas of the thyroid have been produced by goitrogens alone and in combination with the carcinogen acetylaminofluorene. The carcinogenic potency on the thyroid of 32 microcuries of radioactive thyroid was tested in a small series of rats alone, in combination with methylthiouracil, with acetylaminofluorene and with the combined drugs. Radioactive iodine increased the incidence of thyroid adenomas in all groups except those treated with acetylaminofluorene. The adenomas were larger in size as well as in number and showed evidence of malignancy by a gross increase in size and by dissemination outside the thyroid in two instances. The assessment of radiation dosage administered to the thyroid by radioactive iodine is difficult. The percentage of absorption by the thyroid varies with the iodine content of the diet and the surrounding temperature. The authors found it to vary from 10 per cent in hot weather to 30 per cent in cool weather, 24 hours after administration of radioactive iodine. There is a wide variation in concentration from follicle to follicle. The peripheral follicles in the rat take up considerably less iodine than the central follicles. This is only partly balanced by the more rapid disappearance of iodine from the central follicles. The radiation effects are due mostly to beta radiation, since most of the gamma rays, which are much more penetrating, will not be absorbed in the small thyroid of the rat. The human thyroid is 1,000 times heavier than that of the rat, but doses of 10 to 20 millicuries might be regarded as likely to induce adenomas and possibly occasional cancer in the hyperplastic glands. This is just the order of dosage prescribed for the treatment of thyrotoxicosis.

Miliary Tuberculosis: Radiological and Pathological Aspects.—Emery and Lorber report a consecutive series of necropsies in which the diagnosis of miliary tuberculosis of the lungs was established in 52 children under 14. When a discrepancy between the radiological and postmortem findings became apparent, it was decided to obtain a wider opinion on the roentgen appearances. The films were referred to a panel of two radiologists and two pediatricians. The assessors were informed that all these deaths were from tuberculosis and were asked to make a radiological diagnosis of the presence, doubtful presence or absence of miliary tuberculosis. Radiographs of the chest taken within 14 days of death were available in all cases. The fundus oculi was examined for choroidal tubercles in 48 children. The roentgenograms of 18, or about one third of the cases, were studied by the panel. Choroidal tubercles were seen in 25 of the 48 cases. Of the 52 cases, 28 were given diagnoses during the life of the patient. The tubercles were more numerous and larger in the 18 roentgen-positive than in the 34 roentgen-negative cases. Choroidal tubercles were present in a significantly higher proportion in the former (15 of 17) than in the latter (10 of 31). Clinical features consistent with miliary tuberculosis and the presence of early choroidal tubercles establish the diagnosis irrespective of the radiological observations. The present methods of diagnosis of miliary tuberculosis are not sufficiently sensitive.

Cardiac Arrest Relieved by Procaine.—Roualle describes a case of cardiac arrest in which complete asystole persisted for 45 minutes despite cardiac massage and injection of epinephrine (adrenalin®). Normal rhythm was restored after two intracardiac injections of procaine hydrochloride, though the patient survived for only four hours. The immediate use of procaine injected into the heart, in preference to or with epinephrine, is suggested. In view of its delayed action, cardiac massage should be performed to prevent interruption in the cerebral circulation.

Follow-Up of Prefrontal Leukotomy Cases.—Stengel reports a follow-up study on 330 of 345 patients who were subjected to prefrontal leukotomy between 1942 and 1947. The limitations of leukotomy in the treatment of schizophrenic reaction types of disorder and paranoid states have again been demonstrated in these patients. Full remissions have been observed mainly in patients whose personalities and mental conditions had features that are generally regarded as assets from the point of view of prognosis. There is no general consensus as to whether such patients should be operated on. Retrospectively, it is impossible to judge what would have been the fate of the patients who had a full remission following leukotomy if they had not had the operation. That the remission was related to the operation was clear from the fact that leukotomy was followed by immediate or almost immediate improvement. Leukotomy, therefore, set in motion a process that might have taken place without it. Among the various affective reaction types, the results have been relatively most satisfactory in the involutional group, while in patients with manic periods it has been less favorable. The outcome in patients with purely depressive symptoms, i. e., in the recurrent and involutional depressions, was more favorable than in those with manic periods. The planes of the cuts were varied according to the suggestions of the psychiatrists. In certain cases an anterior cut was aimed at, in others a middle or posterior cut, the latter especially in those cases in which general behavior was gravely disturbed, as in chronic catatonics. However, in view of the anatomic observations in the brains of patients who died some time after leukotomy, an attempt at correlating clinical changes with the location of the cuts aimed at by the surgeon seems futile. The emergence and aggravation of antisocial personality features following leukotomy in patients with affective reaction types of disorder has been found to depend not only on the previous personality, but also on certain features of the mental disorder. Epileptic fits occurred in a higher percentage of male than of female patients. Epileptic fits were observed in a much higher percentage of schizophrenic and paranoid patients than of patients with affective reaction types of disorder.

Potentiation of Sulfonamide by L Substance.—Bigger and Ware believe that the sensitivity of a bacterium to sulfonamides is grossly underrated when ordinary culture media are used. Treatment of such media by the method of Harper *and Cawston increases the apparent sensitivity of the bacterium* to sulfonamides, but only to a limited extent.. Bacterium coli, which grows well in a simple synthetic medium, is much more sensitive to sulfonamides in a synthetic medium than it is in mediums treated by the method of Harper and Cawston. The authors describe an improved synthetic medium. The action of sulfathiazole on Bact. coli in synthetic medium is bacteriofrenic rather than bacteriostatic or bactericidal. The addition of a small amount (1 : 20,000) of lemco® (meat extract preparation) to synthetic medium potentiates sulfathiazole so that its action is bactericidal. The substance responsible for the potentiating action of lemco is present in meat extracts, serum, red blood cells, urine and yeast. The provisional name, L substance, has been given *to this constituent of lemco.®* The L substance, which is basic, has been concentrated and partially purified but not yet identified. Since L substance is present in various body fluids that contain little, if any, sulfonamide antagonizers, it is suggested that, in the living body, the action of sulfonamides is bactericidal rather than bacteriofrenic or bacteriostatic, and that, to explain their therapeutic effect, it is unnecessary to evoke the ordinary defence mechanisms of the body. The L substance differs from the substance in horse erythrocytes that is responsible for the Harper and Cawston effect.

Poliomyelitis and Tonsillectomy.—According to Dunn, there exist two groups of critics with regard to poliomyelitis and tonsillectomy. One group advises caution and cessation of tonsillectomy during the epidemic period of poliomyelitis. The evidence to support this advice. Quoting chiefly from the American literature, Dunn finds that "we are back where we started." Although a few writers have claimed that the tonsillectomy-poliomyelitis sequence is coincidental, they do not suggest that the operation be performed when the number of cases has reached epidemic proportions. The type of poliomyelitis otolaryngologists suggest that the physicians have *insufficient* following tonsillectomy is usually bulbar. Numerous cases of bulbar poliomyelitis following tonsillectomy have been reported. If the still undetermined risk of removing tonsils and adenoids during the poliomyelitis season is to be reduced by means other than postponing the operation, there is a need for (1) a practical method of determining the presence, or absence, of the poliomyelitis virus in the prospective patient and (2) a practical method of obtaining information concerning the incidence of poliomyelitis victims in the vicinity of the prospective tonsillectomy patient s home and school The risks involved in tonsillectomy during the epidemic season should be considered, together with the other numerous hazards of tonsillectomy and the urgency of indications for the operation

*Medical Aspects of Hair Dyeing E W P Thomas —p 171

Medical Aspects of Hair Dyeing —Thomas points out that until comparatively recently the only dyes available were either natural vegetable colors or metallic salts, sometimes used in combination Hair dyeing was revolutionized in about 1880 by the discovery of the synthetic organic dyes, paraphenylenediamine and allied chemicals Hair dyes of the paraphenylenediamine group are potential skin irritants in the class known as sensitizers They are contact allergens able to create a state of epidermal sensitization, which manifests itself as an eczematous dermatitis in the area of contact Only a small proportion of those exposed acquire sensitization An estimate that 4 per cent of the general population have an idiosyncrasy toward this chemical is now regarded as far too high, nevertheless, the dye is a skin sensitizer and is responsible for nearly all cases of hair dye dermatitis, as well as being a cause of occupational dermatitis among hairdressers A patch test should be carried out before each application of a para dye, whether the dye be used for the whole head or merely for touching up All reputable hairdressers recognize that this test should be done, but the client may be impatient Some hairdressers have but a hazy idea of the significance of the skin test and believe that once the hair has been dyed without ill effect the dye can be used thence forward without fear. Allergic sensitization, however, may develop after prolonged periods of use of the dye Patch tests are by no means infallible and, when negative, are no absolute guarantee against dermatitis These dyes should not be applied during pregnancy or menstruation or in the presence of eczema or dermatitis on any part of the body It is also best to avoid them if the general health is below par, when the threshold of skin sensitivity may be temporarily lowered They must never be applied to the eyebrows or eyelashes

*New Treatment for Polyneuritis P Merof —p 715

New Treatment of Polyneuritis —Menof points out that hepatic enlargement and tenderness are commonly encountered in alcoholic and diabetic polyneuritis Evidence of liver damage is present also when polyneuritis is associated with pellagra, arsenical poisoning and pernicious (Addison's) anemia Disturbed liver function due to fatty change might be an important factor in the causation of polyneuritis, and if the liver produces or stores a substance necessary for the nutrition of nerve tissue, it is conceivable that this might be diminished in the aforementioned disturbances Since vitamin B_{12} rapidly counteracts the neurological symptoms of pernicious anemia, Menof administered it to patients with alcoholic or diabetic polyneuritis The dosage was considerably larger than that recommended for the treatment of pernicious anemia. The author began with 60 micrograms and finally gave as much as 210 micrograms in one injection The best result was achieved with this large dose Apart from a little localized tenderness owing to the large size of the intramuscular injection (7 cc), no untoward effects were experienced either with this or with any other of the doses used The injection was usually given into the gluteal region The 11 reported case histories indicate that the results of the treatment were encouraging The author feels that equally satisfactory results might be obtained in other forms of polyneuritis and in other nervous disorders associated with chronic alcoholism, e g delirium tremens, Korsakoff s psychosis, superior hemorrhagic polioencephalitis (Wernicke's encephalopathy) and alcoholic hallucinosis These conditions might well result from malnutrition adversely affecting the liver This new therapeutic weapon might also be used in such diseases as progressive muscular atrophy

*Insulin Tolerance Differences in Insulin Shock Doses W Winkler —p 619

Ocular Changes in Prognosis of Tuberculous Meningitis —Heinsius points out that since streptomycin has been used in the treatment of tuberculous meningitis and in miliary tuberculosis, the longer survival of these patients has disclosed a higher incidence of ocular changes Eye involvement is now observed in 92 per cent of these patients, whereas the percentage formerly varied between 50 and 75 per cent There is a certain parallelism between the ocular and general changes Repeated ophthalmologic studies on 98 patients (81 with tuberculous meningitis and 11 with miliary tuberculosis) convinced the author that the ocular changes may even furnish prognostic data He compares records of ocular changes before and since the streptomycin era Choked disk was observed formerly in only about 30 per cent of the cases, whereas now it is present in nearly 60 per cent The prognostic significance of the ocular changes is especially noticeable in stasis symptoms, such as in papillary edema, choked disk and venous stasis As these symptoms subside, a tendency to improvement in the general condition becomes evident, the temperature decreases and the sensory functions and mental status show improvement If, on the other hand, the symptoms of stasis increase, the general condition and sensory activity also become impaired and the temperature usually rises. Optic atrophy usually indicates a fatal termination. Oculomotor paralysis and prolonged pupillary disturbances also indicate a serious condition and an unfavorable prognosis. The appearance of new foci in the choroid are regarded by Walsh as indicative of an unfavorable prognosis, but the author and others regard them as a manifestation of a new hematogenous dissemination, which can be cured by streptomycin therapy. Photophobia and retardation of the pupillary reaction, which may be mistaken for pupillary rigidity and defective convergence, are cited by the author as early symptoms of tuberculous meningitis. In view of the great importance of ocular symptoms in the prognosis of tuberculous meningitis and miliary tuberculosis, whenever streptomycin therapy is employed in these conditions, ophthalmologic control examination should be made once or twice a week.

Insulin Tolerance.—Winkler and Froeschlin made insulin tolerance tests on three groups of students of either the pyknic, leptosomatic or athletic type. They found that in those of the pyknic type the early decrease in blood sugar content is followed by an effective counterruglation, which brings the blood sugar level again to normal or even above it. This again is followed by a decrease. This gives the blood sugar curve a wavelike appearance. Leptosomatic persons also show a rapid decrease in the blood sugar, but the counterregulation is slight. The test curve is characterized by a steep decline and a restless zigzag outline. In persons of the athletic type, the decrease in blood pressure is retarded and the curve is flat, the counterregulation being rather weak. These results indicate that the contrainsular regulation of the blood sugar varies in the different constitutional types. Persons of the pyknic type have a relatively well functioning adrenal system, and their hypophysial counterregulation also is superior to that of the other constitutional types.

Differences in Insulin Shock Dose.—Winkler says since insulin tolerance tests indicated a stronger counterregulation in persons of the pyknic type, it seemed likely that persons of this type would require larger doses of insulin during shock therapy. The first shock treatment is a fairly exact indicator of the insulin tolerance. The first shock dose has been known to vary in extreme cases between 8 and 1,000 units, but usually between 60 and 200 units. Successive shock treatments often require increased doses, but smaller doses may occasionally suffice. On investigating the records of 817 patients who had been given insulin shock treatment and grouping them into constitutional types (312 leptosome, 125 pyknic, 72 athletic and the remainder mixed), the author found that patients of the leptosomic type required much smaller doses of insulin (97 to 110 units) for the induction of shock than did the pyknic types (140 to 170 units) and that the doses for the athletic types were about intermediate between these two. Thus the figures on the insulin shock doses corroborate the results of the insulin tolerance tests.

Penicillin in Treatment of Scarlet Fever.—Lasch reviews observations on 270 scarlet fever patients who were treated between January 1946 and March 1950. The chief aim was to ascertain the efficacy of penicillin therapy. The patients treated during 1946 and 1947 received no penicillin. In 1948 the supply of penicillin was still inadequate, and only patients with severe forms of scarlet fever were treated with it. During the first six months of 1949, alternate patients were treated with penicillin, and after that all patients were given penicillin. In all, 134 patients were treated with penicillin and 136 served as controls. Penicillin therapy transformed scarlet fever into a mild disease. The incidence of suppurating complications, such as otitis, polyarthritis, acute, diffuse glomerulonephritis and septic jaundice was greatly reduced. Myocarditis and nephritis were not prevented, although they were generally mild. The total dose of penicillin was usually from 1,000,000 to 2,000,000 units. Penicillin therapy was occasionally followed by a relapse, suggesting that the development of immunity was inadequate. In spite of these disadvantages, the author feels that penicillin should be given routinely to patients with scarlet fever, because with isolation of the patient and with proper control examinations of pharyngeal smears, these disadvantages can be largely avoided. Penicillin therapy insures rapid clinical cure and prevents serious complications. If complications do develop, they can be controlled with higher dosage. The rapid defervescence and clinical cure quickly makes patients convalescent and reduces the work of the nursing personnel.

Streptomycin Therapy in Vertebral Tuberculosis.—In the 10 cases of vertebral tuberculosis treated by Haizmann and Brändle, there were present extensive gravitation abscesses and profusely discharging fistular openings. The general condition and the appetite were extremely poor. The blood sedimentation rates were greatly accelerated. The temperatures were those characteristic of a septic process. Neither sulfonamide nor penicillin therapy had proved effective. Thoracic vertebrae were involved in five, the lumbar vertebrae in four and the ileosacral joint in one. Streptomycin was given twice daily in individual doses of 250 mg. The daily dose was increased to 1 Gm. in exceptional cases only. The total dose of streptomycin varied between 38 and 86 Gm. The effect of the treatment bordered on the miraculous. In nine of the cases the fistulas closed completely in three months and the secretion had stopped even before that. There was no recurrence after streptomycin therapy was discontinued. The fever subsided, and the sedimentation rate became normal. The weight and the general condition improved. Roentgenoscopy revealed improvement corresponding to the clinical betterment. This report must be regarded as preliminary. Its purpose was to call attention to the life-saving effect of streptomycin, which has never been equalled by any other therapeutic substance.

Increased Sensitivity to Opiates and Barbiturates in Anoxia.—Meyler points out that textbooks usually warn against the use of morphine in attacks of bronchial asthma. He cites a man with bronchial asthma in whom administration of a barbiturate and of morphine was followed by deep coma. In a woman with pulmonary edema, morphine injection was followed by respiratory arrest and death. Increased sensitivity to opiates and barbiturates has been observed in patients with anemia, bronchiolitis and kyphoscoliosis. Such increased sensitivity is likely to exist wherever there are disorders which produce oxygen deficiency, accompanied by a depressive effect of an excess of carbon dioxide in the blood on the respiratory center. Nikethamide or other analeptics may counteract the narcotic effect in such cases.

*Postmenopausal Basedowian Syndrome Cure Obtained with Estrus Producing Compounds, Changes Observed in Extracellular Fluids. R Cachera, M Lamotte and N Masse —p 347

Streptomycin in Addison's Disease—Guy-Laroche and Tremolieres treated *four patients with Addison's disease with* streptomycin. One patient, a man aged 47, had Addison's disease of one month's duration, associated with pulmonary tuberculosis with caseating lesions He had a severe episode of adrenal insufficiency that was resistant to desoxycorticosterone acetate and cortin therapy The adrenal insufficiency was controlled by daily administration of 1 5 Gm of streptomycin The effect of the drug on the pulmonary tuberculosis was highly satisfactory Follow up of the patient showed that for more than one year he did not receive desoxycorticosterone acetate but was able to work The eosinophil count was normal *There was still some hypersensitivity to insulin and a* low 17-ketosteroid level (1 mg per 24 hours) Streptomycin was ineffective in the three patients with mild Addison's disease of one year's duration, without a progressive pulmonary tuberculosis There was no improvement in the clinical picture, and functional tests remained unchanged The dosage of desoxycorticosterone acetate and of cortin could not be reduced Streptomycin caused a mild attack of adrenal insufficiency in one of these three patients and caused an increase in the nitrogen in the urine of all four patients during the first nine days of treatment But this loss of nitrogen was of metabolic and not of clinical importance and did not contraindicate the use of streptomycin These results do not justify streptomycin treatment of Addison's disease in the absence of a progressive tuberculous process Streptomycin is indicated in cases with progressive tuberculous process, pulmonary or any other, if associated with fever or when such a process is suspected because of increased *blood* sedimentation rate and *hyper*globulinemia

Estrus-Producing Compounds in Postmenopausal Syndrome Resembling Toxic Diffuse Goiter—Cachera and co workers report a woman aged 62 in whom menopause had occurred 13 years previously For the preceding six months she had had palpitation, dyspnea on exertion, insomnia, thermophobia, loss of weight and edematous exophthalmos Polydipsia and nocturnal polyuria persisted for several weeks but disappeared spontaneously The thyroid was normal on roentgenologic examination Complete recovery resulted within six months from 28 intramuscular injections of 5 mg of estradiol benzoate followed by three courses of 15 mg of dienestrol given by mouth daily for 20 days Studies of extracellular fluids before treatment showed an increase in fluids similar to that observed in the common types of hyperthyroidism Treatment with massive doses of estrus-producing compounds induced a progressive diminution in the extracellular fluids Within the first three months of treatment, the amount of these fluids was reduced from 14 250 to 12 180 cc, while the body weight of the patient increased simultaneously by 4 4 Kg (10 pounds) The extracellular fluids were restored to normal simultaneously with the disappearance of the symptoms of toxic diffuse goiter The effect of the estrus producing compounds on the extracellular fluids in the patient was opposite to that exerted by these compounds in normal women The effect, therefore, was one of suppression of the hyperthyroidism itself

*Health of Blood Donors After Repeated Blood Donations E Pulitano and M Gaetano —p 877

Blood Donors.—Pulitano and Gaetano report observations on 91 professional blood donors These belonged to one of the four groups of the AB, A, B or O types and were either Rh positive or Rh negative They were all voluntary donors in good general health, of normal body weight and with normal arterial tension Fifty-two donors had been giving blood for several years, and 39 had been giving blood during the last year The donors were between 30 and 60 years old, with the exception of two men of 65 years The withdrawal of blood amounted to from 200 to 400 cc The lapse of time between two consecutive withdrawals was two to three months The number of blood donations varied between 30 and 207 in the group of long term donors, and between 10 and 29 donations in the recent group The determinations were made two or three months after the last blood withdrawal Repeated blood withdrawals *did not appear to have unfavorable effects for the* donors Blood donation does not influence the body weight, the general health, arterial blood pressure or the morphology of the blood In rare instances of donors who had given a large number of blood donations, it was found that either the erythrocytes were smaller than normal, or that there was moderate hyperglobulia or moderate hypochromic anemia. The proteins in the blood of the long term donors were diminished. The sedimentation rate of the erythrocytes was increased. Blood donors should be given a diet rich in proteins and iron as a preventive measure against anemia.

*Streptococcus Sanguis White in Subacute Bacterial Endocarditis. D. P. de Carvalho Lima.—p. 71.

Streptococus Sanguis in Subacute Bacterial Endocarditis.—De Carvalho Lima studied strains of streptococci that he had isolated from the blood of two patients with subacute bacterial endocarditis and three control strains that had already been classified as Streptococcus sanguis. They corresponded to the serologic types 1, 2 and 3. Streptococcus sanguis is the type of streptococcus most frequently found in the blood of patients with subacute bacterial endocarditis. This type of bacterial endocarditis can be controlled by large doses of penicillin administered for a considerable period of time. The Streptococcus sanguis can be differentiated from other streptococci of the viridans group by the fact that it grows in a medium containing 40 per cent bile, that it hydrolyzes arginine, produces dextran in a broth containing 5 per cent saccharose and does not reduce litmus milk. It is differentiated from enterococci by the fact that it does not tolerate a temperature of 60 C. for 30 minutes and will not grow in a medium containing 6.5 per cent of sodium chloride. Blood for cultures should be taken before administration of penicillin.

*Treatment of Advanced Mammary Cancer with Male Sex Hormone. P. Ricklin.—p. 902.

Male Sex Hormone in Advanced Mammary Cancer.—Ricklin treated with testosterone proprionate 12 women with advanced mammary cancer. Some of these had a tumor which was inoperable and others presented extensive skeletal and soft tissue metastases The patients were given 300 mg. of the drug per week, with a total dose of 3,000 to 7,000 mg. One patient with massive metastases of lungs and liver died on the sixteenth day of treatment. Seven patients died within five to 17 months after institution of the testosterone propionate therapy. The four living patients were treated for 4, 6, 7 and 12 months, respectively. Five of the 11 patients showed objective improvement, which was maintained on the average for eight months. It consisted of regression of the primary tumor and regional metastases in the lymph nodes, calcification of osteolytic skeletal metastases or rapid consolidation of pathological fractures. There was no improvement in advanced metastases of the liver and lungs. Subjective improvement in the general condition and relief of pain for at least two to three months was observed in six patients. Favorable experiences by other authors with bilateral ovariectomy and hormone therapy in younger patients was confirmed by the authors in one patient aged 42. Testosterone propionate does not cure mammary cancer but is a valuable palliative.

Effect of Hypophysis Implantation on Lesions of Bone Marrow with Agranulocytosis. K. Fellinger, F. Kaindl and E. Reimer.—p. 931.
*Administration of 2,3-Dimercaptopropanol (BAL) in Diffuse Impairment of Liver Parenchyma. T. Janovics and J. Takó.—p. 933.

Complications of Q-Fever.—Moeschlin and Koszewski report on 50 patients with clinical diagnosis of Q-fever established by serum tests. Nine of the 50 patients had extrapulmonary complications. Five had thrombophlebitis with pulmonary embolism, three had epididymitis, one had encephalitis and one had pancreatitis. Only one of the nine patients with meningeal symptoms had an increase of cells in the cerebrospinal fluid. The extrapulmonary complications occurred after remission of the pulmonary symptoms, between the fourteenth and twenty-third day in the cases with thrombophlebitis, on the eighteenth day in the case of encephalitis and between the twenty-sixth and forty-third day in the cases of epididymitis and pancreatitis. These complications are probably specific rickettsial disorders. Five weeks after the onset of Q-fever, urine from a patient with epididymitis, when inoculated into guinea pigs, proved indirectly the presence of rickettsia by the development of a positive complement reaction in the blood of the inoculated animals. The relatively high incidence of complications in patients with severe Q-fever makes early discharge from the hospital inadvisable. Patients should not be permitted to resume their occupations earlier than three to four weeks after complete defervescence.

Dimercaprol (BAL) in Diffuse Impairment of Liver Parenchyma.—Rapid clinical improvement obtained with dimercaprol (BAL) in four patients with hepatitis occurring during treatment with neoarsphenamine induced Janovics and Takó to treat 38 of 63 patients with acute diffuse liver disturbance with the drug. In the course of five days, 1,100 Gm. were administered, 300 Gm. on the first and second days, 200 Gm. on the third and fourth days and 100 Gm. on the fifth day. Treatment with dimercaprol was instituted when bed rest, Morisson diet, administration of vitamin B, adrenal cortex extract, insulin, choline derivatives and supply of fluids proved ineffective. Diminution in the size of the liver was observed the day after treatment with dimercaprol was discontinued. Liver tenderness subsided, and bile could be aspirated with the duodenal tube in all the patients. The bilirubin content in the urine was minimal, the urobilin was increased. The iodine reaction of bilirubin in the urine was negative, when the bilirubin content of the serum still varied between 6 and 8 mg. per 100 cc. The improvement in the clinical picture and in the laboratory observations was more pronounced in patients who were treated with dimercaprol than in those to whom it was not given. Results of examination of 16 patients three months after and of six patients six months after dimercaprol therapy was discontinued were highly satisfactory. Dimercaprol, similar to glutathione and a substitute for this reduced substance, activates the enzymes containing the sulfhydryl group by keeping the sulfhydril group in a reduced stage. Dimercaprol also transmits its own sulfur atom to the tissues. It thus plays an active part in the production of enzymes.

*"In Vitro" Test of Tolerance to Heparin in Hemorrhagic Syndromes and in Thromboses. J. P. Soulier and Le Bolloch.—p. 3702.

Acute Leukemia.—Tzanck and co-workers report on 60 patients with acute leukemia. Abnormal bleeding occurred in every patient in the course of the disease, but cutaneous and mucosal hemorrhages were predominant. Petechiae were present in 57 patients, ecchymoses in 32 and bleeding from the gums and epistaxis in 31. Gingival bleeding seems to be associated with stomatosis, an early manifestation of acute myeloblastic leukemia and consequently occurs more frequently in adults. Cerebromeningeal hemorrhages occurred in six patients treated with 4-aminopteroylglutamic acid (aminopterin) and is to be considered a serious complication of this method of treatment. Biologic studies of blood constituents suggested a severe disturbance of the three stages of the clotting process. The pronounced prolongation of the bleeding time and the changed capillary fragility indicated a disturbance of the first or capillary stage. Thrombopenia with total loss of retractability of the clot demonstrated a disturbance of the second stage. Mild hypoprothrombinemia and the disturbance of the prothrombin consumption are characteristic of the impairment of the third stage. Studies of the tolerance of the leukemic plasma to heparin and to protamine in vitro and of the protamine index of the amount of protamine required for coagulation of heparinized blood demonstrated that the blood of patients with acute leukemia does not contain excessive amounts of a heparin-like substance and showed that thrombopenia is responsible for the disturbance. This thrombopenia is linked with inhibition of the megakaryocytes. Hemostasis in acute leukemia may be obtained, at least temporarily, by exchange transfusions and intravenous administration of protamine sulfate combined with local hemostasis by means of gelatin tampons and 500 units of thrombin.

In Vitro Test of Heparin Tolerance.—Soulier and Le Bolloch performed a modified Waugh-Rudick test for increased coagulability of the blood on 146 patients with various disturbances of the clotting process and on 60 control persons. Nine patients had hypoprothrombinemia, eight had thrombopenia, seven were hemophiliacs and two had fibrinopenia. Additional patients had a simultaneous deficiency of several clotting factors, and others had hemorrhagic syndromes of distinctly vascular origin. Twenty-two patients had thrombosis. The authors believe that the in vitro test of tolerance to heparin is superior to other tests by which the total coagulability of the blood may be measured, such as Howell's clotting time test, Allen's protamine index and Takat's in vivo test of tolerance to heparin. Determination of the number of platelets, of the fibrinogen level or of the prothrombin level may be valuable but is not as useful as the heparin tolerance test, which conclusively determines decreased or increased coagulability. The isolated deficiency of one of the clotting factors does not prevent the occurrence of a thrombosis, even in the presence of a mild total hypercoagulability. The heparin tolerance test and the evaluation of one or the other of the deficient factors supplement one another. The determination of the prothrombin consumption in the course of the clotting process aids in the evaluation of the first stage of this process and protects against the variations of the fibrinogen, but it does not provide any information about increased coagulability and is therefore of no aid in the diagnosis of thrombosis. The tolerance test is an aid to diagnosis of hemorrhagic diathesis by detection or confirmation of a decreased coagulability and of thrombosis by demonstration of an increased coagulability. It is a guide to treatment with anticoagulants because it facilitates the choice of the drug and of its effective dosage.

BAL Treatment of Hematological Complications After Sanocrysin. H. Brodthagen.—p. 1227.

Anticoagulants in Treatment of Coronary Occlusion.—Holten states that treatment of coronary occlusion with anticoagulants reduces considerably the mortality in this disease. Of 430 patients with coronary occlusion treated in various medical departments in Denmark from June 1948 to June 1950, 174 admitted on even dates were given heparin for 24 hours and bishydroxydicoumarin (dicumarol®) for three weeks and 250 admitted on odd dates received no anticoagulants. The bishydroxydicoumarin dosage was based on frequent determinations of the prothrombin time, the aim being a reduction to about 30 per cent of the normal. The treatment was otherwise the same for the two groups. Of the first group, 39 (22.5 per cent) died, of the second, 92 (36 per cent) died. The improvement in prognosis was most pronounced in the age group 60-69, in which the mortality was 17 per cent among the patients given anticoagulants as against 43 per cent among those not given anticoagulants. During anticoagulant treatment, thromboembolic complications occurred in seven patients (4 per cent) and in 36 patients (14 per cent) in the control group in the same period. The number of deaths in the first week of treatment was 11.5 per cent in the first group and 19.5 per cent in the second. An important part of the effect of the treatment is believed to depend on prevention of growth of the thrombus. The anticoagulant treatment seemed significantly to improve the prognosis in patients who had had earlier attacks of coronary occlusion; of 25 such patients treated, five died, while of the 32 untreated, 15 died.

Water Metabolism and Mineral Salt Excretion in Patients with Hepatic Diseases and Effects of Desoxycorticosterone Acetate. L. Benda and E. Rissel.—p. 456.
*Ligature of Superior Vena Cava. E. Strahberger.—p. 462.
Roentgen Picture of Phlegmon of Small Intestine. P. Lutz.—p. 466.

Ligature of Superior Vena Cava.—Strahberger believes that ligature of the superior vena cava, provided that it does not include the vena azygos, is not a life-threatening procedure and may be employed in the course of surgical intervention for bronchial carcinoma invading the vein. His opinion is based on postmortem observations of cases of complete occlusion of the superior vena cava cited in the literature. Experiments in dogs demonstrated the absence of stasis after the ligature of the superior vena cava above the vena azygos. The animals were alert and fresh a few days after the operation. Neither history nor necropsy revealed the presence of stasis in eight persons who had died from bronchial carcinoma that occluded the superior vena cava above the vena azygos. A slight swelling of the neck and face and a mild headache may develop, but these subside with the development of collateral circulation. Enlarged cutaneous veins will not be observed over the thorax and abdominal wall. Occlusion of both the superior vena cava and the vena azygos may lead to severe life-threatening phenomena. Death may result rapidly from stasis in the vital organs, particularly the brain, and from increasing anoxemia. Pronounced venous congestion over the chest and the abdomen is characteristic of a *simultaneous occlusion of the superior vena cava* and vena azygos. Anastomosis after resection of a stenosed portion of the superior vena cava is not feasible, because it cannot be done without tension. Complicated methods of anastomosis are contraindicated in radical intervention for bronchial carcinoma. Resection and ligature of the superior vena cava above the vena azygos may be carried out without great hazard to the patient, provided the general condition and heart function are adequate and provided the vena azygos is normal and is not occluded. Section of superior vena cava and vena azygos will be fatal in the great majority of cases and is, therefore, not permissible.

62:485-500 (July 14) 1950

*Hypoproteinemia in Pernicious Anemia. A. Schneiderbaur.—p. 489.
Addison's Disease and Appendicitis. G. Dettre and Z. Méra.—p. 492.
History of Vienna Medical School (Personal Memories). N. Jagić.—p. 494.
Question of Sciatica or Avulsion of Transverse Process: Contribution to Diagnosis of Sport Injuries of Lumbar Portion of Spine. H. Pototschnig.—p. 496.

Hypoproteinemia in Pernicious Anemia.—Schneiderbaur reports on 37 patients with pernicious anemia, 24 of whom had an abnormal serum protein level. There was an abnormal decrease in the total amount of protein in the blood and in the albumin content. This decrease was severe in 16 patients and milder in eight. The hypoproteinemia was more pronounced in patients with severer pernicious anemia and particularly in those of advanced age. The hypoalbuminemia improved simultaneously with the increase in number of erythrocytes and hemoglobin content following liver therapy. Some of the patients still had a mild hypoalbuminemia, although the red blood cell picture had been restored to normal. Additional exogenous protein supply through blood transfusion appeared indispensable for the relief of hypoalbuminemia. Relation between blood proteins and erythrocytes was demonstrated by the observation of resistance of patients with pernicious anemia to liver therapy in Vienna and elsewhere in Europe during the postwar starvation period of 1945-1946 and of optimal effects of liver therapy with respect to efficiency, duration and prevention of recurrences when combined with blood transfusion. Hypoproteinemia (hypoalbuminemia) occurring under normal nutritional conditions in patients with pernicious anemia is to be considered as endogenous and probably due to disturbance of liver function but may be partly also exogenous if a relative alimentary protein deficiency is present.

BOOK NOTICES

The reviews here published have been prepared by competent authorities and do not represent the opinions of any official bodies unless specifically stated.

Physicians Federal Income Tax Guide and Simplified Accounting Record for the Preparation of 1950 Returns and 1951 Estimates. By Hugh J. Campbell and James B. Liberman. 1951 edition. Paper. $2.50. Pp. 127. Doniger & Raughley, Inc., Great Neck, New York, 1950.

With the approach of the federal income tax return season, physicians will find of interest and benefit the contents of this brochure, which undertakes to state in an understandable way the requirements of the federal law as they apply to physicians. There is a detailed discussion of the deductions a physician may claim, including a two column statement concerning the deductibility of entertainment expenses. While the reader may be a bit skeptical of the advice given on page 37, paragraph 81, that expenditures for funeral wreaths are deductible as "entertainment expenses," the authors do emphasize the requirement that, to be deductible, entertainment expenses must have been incurred for business purposes and that adequate proof must exist not only of the expenditures but of the purpose. That is an important admonition, and physicians will proceed wisely if they keep it in mind in completing their income tax returns.

World Surgery 1950: Technics, Improvisations and Procedures Gathered from the Surgical Literature of the World. By Stephan A. Zieman, M.A., M.D., F.A.C.S. Cloth. $6. Pp. 177, with 53 illustrations. J. B. Lippincott Company, 227-231 S. 6th St., Philadelphia 5; Aldine House 10-13 Bedford St., London, W.C.2; 2083 Guy St., Montreal, 1950.

This volume attempts to survey and present material from the world literature, and emphasizes the newer concepts in surgery. The voluminous material selected shows good organization and lucid presentation. The contents include gastrointestinal surgery, cardiovascular-respiratory surgery, gynecology, obstetrics, orthopedics, genitourinary surgery, neurosurgery and psychosurgery, ophthalmology and otolaryngology and head, neck and miscellaneous surgery. Under the last named heading are included anesthesiology, radiology, preoperative and postoperative care, blood substitutes and antibiotics. At the end of the work is an index of authors and of subjects and the list of journals from which these articles have been abstracted. This book can be recommended as a survey of some of the world surgical literature.

Handbook of Medical Protozoology for Medical Men, Parasitologists and Zoologists. By Cecil A. Hoare, D.Sc., Protozoologist to the Wellcome Laboratories of Tropical Medicine, London. Cloth. $7. Pp. 334, with 43 illustrations. The Williams & Wilkins Company, Mount Royal & Guilford Aves., Baltimore 2, 1950.

This book is by an outstanding, well known protozoologist, and factually it is especially useful. Unfortunately, there is no bibliography associated with the text or as a source of reference material at the end of the book, although the author has obviously drawn widely from the literature for his presentation. His sections on the amebas and the trypanosomes are especially well done, because for a long time the author has been closely affiliated with these fields. There is a short section on each of the parasites, dealing briefly with the clinical aspects and the course of the infections. Admittedly, the amount of clinical material would be inadequate for a clinician, but the author realizes this and so states in his introduction. This book is a valuable addition to the subject of medical protozoology.

Human Sterilization: Techniques of Permanent Conception Control. By Robert Latou Dickinson, M.D., and Clarence James Gamble, M.D. Paper. 25 cents. Pp. 40, with 31 illustrations. Dr. C. J. Gamble, 255 Adams St., Milton, Mass.; Human Betterment League of North Carolina, Box 3036 Winston-Salem, 1950.

This monograph attempts to present, in a semiphilosophical way, the subject of human sterilization. The subject has been oversimplified. The statement that "male sterilization is readily done in the surgeon's office" is not acceptable. Although this might have been accomplished many times, it is surely not to be encouraged or recommended. This subject is timely and has a specific place in medical literature. Unfortunately, the illustrations do not show up to advantage on the poor quality of paper used. Space should have been devoted to complications and their treatments. A rather extensive author index is included.

Clinical Applications of Suggestion and Hypnosis. By William T. Heron, M.A., Ph.D., Professor of Psychology, University of Minnesota, Minneapolis. Cloth. $3. Pp. 116. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This is a short summary of present knowledge concerning hypnosis and a presentation of methods for its professional use by physicians, dentists and clinical psychologists. The author emphasizes that in use of hypnosis the professional man must think of himself in the role of a teacher guiding the patient toward objectives which the patient realizes are to his best interest. Methods for the induction of the hynotic state are outlined, and mention is made of the use of posthypnotic suggestion and group hypnosis. Precautions in the use of the method are outlined. The author recommends that hypnosis be used to a much greater extent in the clinical handling of patients.

It is extremely doubtful whether physicians, dentists or clinical psychologists would be justified in undertaking the use of the hypnotic method with their patients solely on the basis of the information provided here. A much more thorough study of the subject, choice of methods and the mental mechanisms involved would appear necessary for effective clinical use.

Researches on the Measurement of Human Performance. By N. H. Mackworth. Medical Research Council Special Report Series No. 268. Paper. 4s. Pp. 156, with 60 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W.C.2, 1950.

This is an excellent publication. It cannot be recommended too highly for the purpose it intends to serve. The subject matter is divided into two parts. The first part deals with visual and auditory vigilance tests, and results are presented showing that one can avoid the decrease in efficiency, which occurs usually after 30 minutes, by providing shorter periods of duty or by informing the persons on watch regarding their performance. The second part deals with tests for determining the effect of high atmospheric temperatures and of exposure to nonlethal war gases on the performance over long periods of sensory, intellectual and muscular work. For example, results are presented showing that deterioration of performance occurs noticeably at "effective temperatures" above from 83 F. to 87.5 F., that is, at the dry bulb/wet bulb readings of 90/80 F. and 95/85 F. with an air movement of 100 feet per minute. In view of the information provided, the publication should be in every library not restricted to fiction.

Methods of Tissue Culture. By Raymond C. Parker, Ph.D., Associate Professor of Experimental Cytology, School of Hygiene, University of Toronto, Toronto. With a chapter by Joseph F. Morgan, Ph.D. Second edition. Cloth. $7.50. Pp. 294, with 113 illustrations. Paul B. Hoeber, Inc. (Medical Book Department of Harper & Brothers), 49 E. 33rd St., New York 16, 1950.

The first edition of this book was published in 1938 and incorporated the technics employed by the late Dr. Alexis Carrel. The new edition retains many of the original sections, although these have been extended by the inclusion of procedures which are presently generally accepted. The subject is concisely and clearly presented, and details of procedures and formulas are adequate. The text is well illustrated, and more than 200 references are cited.

The 1949 Year Book of Endocrinology, Metabolism and Nutrition (December 1948 - January 1949). Endocrinology. Edited by Willard O. Thompson, M D., Clinical Professor of Medicine, University of Illinois College of Medicine, Chicago. Metabolism and Nutrition. Edited by Tom D. Spies, M D., Chairman, Department of Nutrition and Metabolism, Northwestern University School of Medicine, Chicago. Cloth. $1.75. Pp. 550, with 101 illustrations. The Year Book Publishers, Inc., 200 E. Illinois St., Chicago 11, 1950.

This is an attempt to abstract the important literature of the year on endocrinology, metabolism and nutrition, with editorial comment on the findings. In reviewing the editor's comments on pituitary adrenocorticotropic hormone (ACTH) and cortisone, it is interesting to note that an excessive secretion of potassium is reported as producing dangerously low levels of potassium concentration in body fluids. Also, the categorical statement is made that patients treated with these agents have shown all manifestations of Cushing's syndrome. To date, the thin skin, the ecchymoses and polycythemia of Cushing's syndrome have not been reported following pituitary adrenocorticotropic hormone or cortisone therapy. Whether these additional observations will be encountered following administration of these agents over a longer period remains to be seen. In discussing pulmonary tuberculosis, the statement is made that ". . . production of tubercle bacilli appears not to be affected, and if the ACTH administration is discontinued, a severe relapse occurs." This is probably another error in the publication. In all likelihood, reproduction of tubercle bacilli was meant in this case.

Selye's theory of the general adaptation syndrome and stress seems inadequately interpreted, since the editor apparently disregards the exhaustion phase occurring in chronic stress and does not suggest that certain disease states may ensue either from exhaustion or from overreaction of the defense mechanism to stress. Of interest in the metabolic studies outlined were Jorpes' recrystallization of insulin with reduction of insulin sensitivity in patients with allergy to the hormone and the successful use of protamine zinc insulin injection and cholesterol implants by Vargas. The review of sodium chloride restriction in hypertensive vascular disease and the presentation of low sodium diets is of timely interest. The difficulties of assembling a book of this type are manifest, but editorial comments should be reviewed with care and rectitude.

The Sulphonamides. By F. Hawking, M D., and J. Stewart Lawrence, M D., M R.C.P., Physician-in-Charge of the Walkden Clinic, Manchester. Cloth 42s Pp 389, with 46 illustrations H. K Lewis & Co., Ltd., 136 Gower St., London, W.C.1; Grune & Stratton, Inc., 381 Fourth Ave, New York 16, 1950.

There have been many books and monographs written about the sulfonamides, but in recent years the popularity of the antibiotics has caused a lack of interest in these older chemotherapeutic agents. Nevertheless, the sulfonamides are still valuable drugs and have a rightful place in medicine. Drs. Hawking and Lawrence have done an excellent job in reevaluating the sulfonamide compounds, and their book is one of the most complete yet published. The introduction contains a brief history of the discovery and development of sulfonamides. The principal chemical reactions of these compounds are briefly presented, and the chemical formula and physical and chemical properties of each of the available drugs is given. Most valuable is the list of 236 trade names for sulfonamide drugs, for which the common or chemical name is given. The nomenclature problem, especially in Europe, is exceedingly confusing, there being 64 different trade names for sulfanilamide alone.

The mechanism of action of the sulfonamides is adequately discussed, and the antibacterial spectrum of the various derivatives is presented. The problem of bacterial resistance is also discussed. The material on pharmacology, mode of administration and principles governing the choice of compounds for specific injections is well written. Not all American workers will agree with some of the recommendations, but the discussions are adequate and convincing. The authors also present their concept of when sulfonamides should be preferred to penicillin and vice versa. A major portion of the book concerns the use of various sulfonamides in a variety of infections. Although it is obvious that the British use more sulfonamides in proportion to the antibiotics than do their American colleagues, the documentation and objective reasoning for each of the recommendations made is impressive and convincing.

The last portion of the book concerns toxicity and sensitization to the sulfonamides. It is apparent that the British have seen less toxicity to the sulfonamides than have American physicians. This may reflect a more judicious use of these compounds on their part and an alertness to the early signs of toxicity, with consequent prevention of some of the more serious sequelae reported in the American literature. The authors, however, evaluate critically the evidence regarding clinical toxicity, and their conclusions are well supported by this evidence. This book is obviously the most thorough and fundamental treatise on the sulfonamides yet published. It can be used profitably by physicians throughout the world and is of particular value to internists and pediatricians.

The Rhesus Danger: Its Medical, Moral and Legal Aspects. By R. N. C. McCurdy, M B., Ch B., D.P.H. Paper. 5s. Pp. 138. William Heinemann, Ltd., 99 Great Russell St., London, W.C.1, 1950.

The author of this book, himself a victim of Rh sensitization, which affected two of his children, has made a thorough study of the subject. This interesting monograph is the fruit of his labors. The book is written primarily for the information of patients confronted with the problem, but also can be read with profit by physicians. In the first part of the book, comprising 48 pages, a lucid description is given of mendelian inheritance, the blood groups, the discovery of the Rh factor, Rh sensitization and its effects and the present method of treatment of erythroblastosis fetalis. In this section are presented some interesting statistical estimates of the incidence of erythroblastosis fetalis. The author exaggerates somewhat the danger of cerebral sequelae in infants who survive, considering that recent observations show that such sequelae are rare among babies treated by exchange transfusion.

In the second section of the book, the author discusses the alternatives open to the luckless couple in whom the husband is homozygous Rh positive and the wife Rh negative and so strongly sensitized that every Rh-positive fetus will almost surely be stillborn. He discusses in turn the medical, moral and legal implications of contraception, sterilization, therapeutic abortion, adoption, artificial insemination from a donor and divorce. While no final conclusion concerning any of these solutions is possible at the present time, the author has succeeded in presenting an interesting account of these controversial matters.

There are remarkably few misstatements in the monograph, which can, therefore, be safely recommended as an introduction to the subject. This being a British publication, the CDE notations are used with the usual confusion between genotypes and phenotypes; for example, on page 20 the author states, "A person's red cells must contain three pairs of Rh genes. . . ." At times the author indulges in speculation, as when he suggests treating the semen of heterozygous husbands with anti-Rh serum in order to immobilize or kill the spermatozoa carrying the Rh-positive gene. Another fanciful suggestion is the idea of preparing an antibody against Rh antibodies, in order to neutralize the Rh antibodies and prevent their harmful effects. The monograph fills a real need, and its few slight imperfections will hardly interfere with its popularity.

Selective Partial Ablation of the Frontal Cortex: A Correlative Study of Its Effects on Human Psychotic Subjects. By The Columbia-Greystone Associates. Edited by Fred A. Mettler, M.D., Ph D. Problems of the Human Brain. Cloth. $10. Pp. 517, with 122 illustrations. Paul B. Hoeber, Inc., Medical Book Department of Harper & Brothers, 49 E. 33rd St., New York 16, 1949.

This is a well documented report of a thorough study of 24 cases of mental disease in which selective ablations of specific areas of the frontal cortex were carried out. This new selective operation is called topectomy by the authors. It consists of removal of a specific area of gray matter, in contrast to the standard form of prefrontal lobotomy, which consists of incisions into the anatomically less well differentiated white matter (leukotomy).

In addition to the 24 patients on whom topectomy was performed, 24 control patients were studied with equal thoroughness; in eight of these the standard leukotomy was performed.

The authors embarked on their new surgical approach in an effort to discover whether small and specific ablations of well circumscribed areas of the frontal cortex might have the same beneficial effects that leukotomy (the standard form of prefrontal lobotomy) does without the undesirable but unavoidable side effects of the extensive standard operation They also wished to discover which areas would have to be ablated to achieve these results Prior to this work, it was an open question whether the extent of the operation per se had anything to do with its effects (a not inconceivable possibility in view of the results of Lashley's work on animals) or whether interference with certain specific cortical systems was responsible for the desirable results If the latter were the case, then certainly it should be possible to minimize the undesirable side effects by narrowing the area operated on It was the wise decision of the authors to remove the much better defined cortical areas rather than the interwoven and anatomically far less differentiated fiber tracts of the white matter

Although the authors' series of cases was small, they nevertheless have produced convincing evidence that the beneficial effects of frontal lobe operation are not based on the total amount of frontal lobe tissue removed No correlation was found between the clinical result and the amount and weight of gray brain tissue removed On the contrary, desirable clinical results were found to be based on the removal of, or significant encroachment on, areas 9 and 10 as well as the small adjacent area 46 In the 13 of the 24 patients on whom topectomy was performed and in whom interruption of psychotic behavior resulted, one of these three areas had been removed wholly or in part Of those patients in whom one of these three areas had not been encroached on, none recovered Careful postoperative electroencephalographic study showed that of the 24 patients subjected to topectomy, 13 continued to show electroencephalographic abnormalities over the first 30 postoperative days, in nine cases this abnormality continued for six months after operation Epileptic seizures occurred in five of the 24 patients (one to nine seizures each) These figures suggest that these postoperative complications exceed those which occur in standard lobotomy This increase in cerebral dysrhythmia may be a drawback of the method unless formation of epileptogenic scars can be prevented by further advances in technic

Nevertheless, the important results that the authors have obtained with their method of localized cortical ablations will undoubtedly be a valuable incentive to improvement of the clinical results of lobotomy by more limited and circumscribed incisions into the white matter, and these efforts will be significantly aided by careful study of cortical ablations performed by the authors This book is an important landmark in the development of the surgical approach to the treatment of mental illness, and its perusal will be essential to all who perform or recommend psychosurgery

Physical Chemistry for Premedical Students By John Page Amsden Professor of Chemistry, Dartmouth College, Hanover, N H Second edition Cloth $4 25 Pp 317, with illustrations McGraw-Hill Book Company, Inc 330 W 42nd St, New York 18, Aldwych House, Aldwych, London W C 2 1950

This is a short textbook written especially for the busy premedical student It makes no claim to complete coverage of physical chemistry Many important subjects have been sacrificed in deference to an overloaded time table The development of some of the subjects included in the text has been curtailed for the same reason The important subject of thermodynamics, however has been added to the present edition The material for the most part is clearly presented In some instances, as in the definition of the order of a reaction, the phraseology appears awkward Clarity, in such cases, is usually restored by the judicious use of examples

The mathematical requirements for comprehension of the text are limited to a knowledge of quadratic equations and the use of logarithms, except in the few cases where calculus is essential Problems are presented at the end of each chapter The author's careful selection of subjects and the clarity of their presentation should insure the wide use of this textbook in premedical schools

The Mental Health Programs of the Forty-Eight States: A Report to the Governors' Conference Paper $4 Pp 377 The Council of State Governments, 1313 E 60th St, Chicago 37, 1950

This is a comprehensive and challenging report on the present status of mental health programs in the 48 states, with emphasis on mental hospital care The information was gathered by a special research staff by means of questionnaires and other information obtained from the offices of the governors of the 48 states and from state mental health and hospital authorities There are over 100 pages of detailed tabulations, describing organization, appropriation, costs, personnel, conditions of buildings and numerous other aspects of mental hospital care It is startling to find, for example, that the average annual expenditure for patients varies from a little over $400 a year in Tennessee to $1,100 in Wisconsin Many of these disparities cannot be explained by regional differences The report cites an estimated total of 326,000 additional mental hospital beds needed, as of Jan 1, 1950 Overcrowding and the need for additional personnel are stated to be the two most important problems in mental hospital care The report recognizes also that not enough emphasis is being placed on active treatment of patients after admission Recommendations made include increased state hospital space, more modern equipment, more and better personnel and the establishment of preventive programs, including mental health clinics outside of hospitals, child guidance clinics and follow-up clinics for those on leave from state hospitals The report does not discuss extensively the preventive aspects of mental health but states that "in this field very little is known" The need for research is very properly emphasized This is an excellent general review of the present status of mental health programs in this country and should prove of great value to all those concerned with mental health

A Guide to Psychiatric Books with a Suggested Basic Reading List Compiled by Karl A Menninger, M D, General Director of the Department of Education, The Menninger Foundation, Topeka Kansas With the Collaboration of George Devereux, Ph D, Lecturer in Anthropology, The Menninger School of Psychiatry and the Topeka Institute for Psychoanalysis, Topeka Kansas The Menninger Clinic Monograph Series No 7 Cloth $3 50 Pp 148 Grune & Stratton, Inc, 381 Fourth Ave, New York 16, 1950

The authors have compiled a comprehensive reading list of books on psychiatry to fill the need for a guide for teachers in psychiatry, and ancillary fields, in the planning and development of systems of education The authors note that the list is obviously too long for indiscriminate prescription by teachers in psychiatry and have increased its usefulness by starring of items in each category which appear of outstanding significance The preparation of the book itself and the selection of the starred items was carried out by consultation with many colleagues in the field of psychiatry and in allied fields of psychology sociology, anthropology, nursing and social work Books included are selected only from books published prior to 1949

The list is divided into two parts Part 1, a guide to psychiatric books, includes titles under basic disciplines of the field, titles in the various specialized fields of psychiatry, psychiatric therapies and preventive psychiatry and mental hygiene Part 2 is a suggested basic psychiatric reading list related to the several major groupings mentioned in part 1 Preparation of such a list seems long overdue Undoubtedly it will fill a long-felt need, particularly for persons engaged in planning programs of psychiatric education

Transactions of the American Goiter Association 1949 Annual Session May 26 27, 28, Hotel Loraine, Madison, Wisconsin Cloth $10 50 Pp 460, with illustrations Charles C Thomas Publisher, 301-327 E Lawrence Ave, Springfield, Ill, 1950

This volume contains the papers presented at the twenty-sixth annual meeting of the American Goiter Association A perusal of the contents reveals the increasing interest in the use of radioiodine as a method of both therapy and diagnosis One of the most important essays is on the direct estimation of the rate of thyroid hormone formation in man by the effect of the iodide ion on thyroid iodine utilization

Another interesting report concerned the use of intravenous anesthesia in basal metabolism determination A group of normal subjects as well as patients with certain disease states were tested by this procedure. Normal patients showed a slight drop in basal metabolic rate with this procedure, but this was not below normal range. Patients with severe hyperthyroidism showed little change in the metabolic rate under anesthesia and required larger doses of intravenous anesthetic than the normal patient. Patients with high metabolic rate due to various nervous states had a drop in basal metabolism to normal under anesthesia, thus indicating absence of hyperthyroidism. This method of determining basal metabolism may prove of value in the differential diagnosis of hyperthyroidism. The book as a whole represents a compilation of modern theory and practice in the treatment of the various thyroid diseases.

Lehrbuch der Kinderheilkunde. Von R Degkwitz, et al. Fourth and fifth edition edited by E. Rominger. Cloth 49 80 marks. Pp. 971, with 267 illustrations. Springer-Verlag, Reichpietschufer 20, Berlin W 35, 1950.

It is gratifying to see medical books of quality appear again in Europe. This most recent edition of Rominger's textbook of pediatrics contains contributions of pediatricians well known in this country and well qualified to write their respective chapters. The purpose of the book, as stated by the editor, is to give a basic working knowledge of pediatrics to the medical student and to the general practitioner. This has been ably achieved. The "most important results of research," however, which the authors attempted to incorporate in the text, are to some extent missing. This is probably due to their admitted inability to obtain all the necessary literature from abroad. The German scientific way of writing has unfortunately not changed through the decades. Sentences are unnecessarily long and cumbersome to read. The definition of rheumatic fever, for example, consists of nine lines, eight commas, but no periods.

In comparison with American textbooks, there are some differences in concept of some disease processes. Roseola infantum, for instance, is not considered a separate clinical entity. Erythroblastosis as well as cystic fibrosis of the pancreas are given little space, whereas nutritional disturbances like *Milchnaerschaden* and *Mehlnachrschaden* still seem to play a large role in German pediatric thinking. The discussion of treatment often falls short of its goal. Specific antiepileptic drugs have apparently not yet been given extensive trials. The outline of care for the rheumatic fever patient is but brief.

The book has many excellent illustrations and is well printed on good paper. Yet one would like to see the custom discontinued of printing long passages in fine print, as is commonly done in German textbooks.

The general practitioner as well as the pediatrician will find this textbook a useful reference.

McClung's Handbook of Microscopical Technique for Workers in Animal and Plant Tissues. By Thirty-Five Authors. Edited by Ruth McClung Jones, Professor of Biology, Winthrop College, Rock Hill, South Carolina Third edition. Cloth. $12. Pp. 790, with 157 illustrations. Paul B. Hoeber, Inc. (Medical Book Department of Harper & Brothers), 19 E 33rd St, New York 16, 1950.

Microscopic examination of the cellular elements of plants and animals is an essential procedure in the biologic sciences and a supplementary method in other fields of scientific investigation. Improperly prepared specimens result in errors, misinterpretations and last, but not least, frustration on the part of the technician. Technical skill is the pinnacle of success in the field, but it is necessarily dependent on adequately detailed procedures and formulas which often are lacking in published scientific literature.

This volume, succeeding the 1937 edition of the late Clarence E. McClung, conforms with his policy of including new methods, references, fundamental principles and the characteristics of the cellular components involved. Parts 1 and 2 include the more conventional methods of preparing slides, fixation of tissues and staining procedures. Part 3 describes special procedures, such as micrurgical technic, vital stains, centrifuge microscope, phase microscopy, fluorescence microscopy, radioautographic technic, electron microscopy and microincineration methods. The volume will provide excellent reference material for clinical and pathological laboratories and biologic science departments in universities and medical schools.

Pathologic Physiology: Mechanisms of Disease. Edited by William A Sodeman, M.D., F.A.C.P., William Henderson Professor of the Prevention of Tropical and Semi-Tropical Diseases, Tulane University of Louisiana School of Medicine, New Orleans Cloth. $11.50. Pp. 808, with 146 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St, Shaftesbury Ave, London, W.C.2, 1950.

This book presents the abnormal physiology of internal diseases as viewed by 25 contributors including the editor. The presentation of physiology in this way can be likened to medical pathology presented in the well known monograph, "the Pathology of Internal Diseases," by William Boyd. There is room for this method of dealing with basic physiology, despite the existence of such familiar textbooks as Wiggers' "Physiology in Health and Disease" and Best and Taylor's "Physiological Basis of Medical Practice."

The author seeks to correlate the disturbances in physiology which are related to the clinical manifestations of internal disease. The subject matter is handled by systems and by etiological aspect of disease. The limitations of physiology make it impossible to encompass the various phases of disease presented by standard textbooks of medicine. Nevertheless, the book achieves its primary objective of explaining signs and symptoms in terms of physiology.

The contributors have written for the beginning student, so that the book can be used in conjunction with elementary textbooks of physiology and medicine. This may limit its appeal to physicians and postgraduate students. The references listed at the end of each section are sufficient to stimulate advanced study. Fundamental concepts are properly emphasized. The chapters on infection and allergy involve the science of immunology more than physiology. The typography is pleasing, and the illustrations are clear. A good index is provided. Students and practitioners of medicine will find the book a useful supplement to standard textbooks used in medicine.

Klinik und Therapie der massiven Magendarmblutung. Von Dr. Nicola Markoff, Privatdozent an der Universitat Zurich. Lieferung II, Sammlung innere Medizin und ihre Grenzgebiete, herausgegeben von Prof. Dr. med. P. H. Rossler und Priv. Doz. Dr. med. O. Spuhler, Paper. 11 20 Swiss francs. Pp. 135, with 31 illustrations. Hans Huber, Marktgasse 9, Bern 16, 1950.

The author of this commendable monograph discusses the problems presented by severe hemorrhage from the upper part of the gastrointestinal tract. He reviews a substantial number of previous publications and presents the results of 102 cases. These are summarized in an excellent table beginning on page 102, and 19 of them are presented in greater detail in the text. On page 83 there begins a discussion of the "treatment with food," which seems to have given good results in the author's hands; on this point his experience differs from that reported by J. R. Brown and associates (*Arch. Surg.* **61**: *767-774* [Oct.] 1950). The difference is not surprising, since there are indications that geography influences the relative frequency of various types of upper gastrointestinal disease. On pages 125 and 126, the author gives a compact summary of his convictions as to diagnosis and treatment. The book closes with a bibliography of 268 references, on which the author deserves a special compliment. Whereas some recent books contain bibliographies full of mutilated foreign names and incomplete data, in the present case there seems to be complete accuracy.

A Text-Book of Venereal Diseases. By R. R. Willcox, Consultant in Venereal Diseases, St. Mary's Hospital, London. Cloth. $5. Pp. 439, with 154 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1950.

The author is a well known English venereologist. He is consultant to several of the larger venereal disease clinics in London as well as to the World Health Organization. He has spent much time in Africa, where he has investigated venereal diseases.

This book was written, according to the author, because most of the textbooks on venereal disease were insular and ignored many disorders of venereal or nonvenereal origin which were commonly encountered in many parts of the world. This is a textbook with a global outlook, which deals with the problem of the venereologist not only in temperate climates but also in Central Africa and South Africa The book is divided into three parts; there is no bibliography. The first part deals with gonorrhea and related diseases. The second is concerned with the various types of syphilitic infection as well as yaws, bejel and pinta. The discussion of the latter three diseases is brief but adequate and well illustrated. The third part discusses the drugs and antibiotics used in the treatment of the venereal diseases, as well as prophylaxis and venereal disease control. This section is entirely up to date. The author has written an excellent short textbook on the venereal diseases.

On the Experimental Morphology of the Adrenal Cortex. By Hans Selye, M.D., Ph.D., D.Sc., Professor and Director of the Institute of Experimental Medicine and Surgery, University of Montreal, Montreal, Canada, and Helen Stone, B.Sc. Publication Number 74, American Lecture Series, A Monograph in American Lectures in Endocrinology, edited by Willard O. Thompson, M.D., Clinical Professor of Medicine, University of Illinois College of Medicine, Chicago. Cloth. $2.25. Pp. 105, with illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This small monograph was issued presumably in response to the present interest in the adrenal cortex but would have appeared more appropriately as an experimental study in one of the usual journals. The authors have studied the effects of variations in the protein and salt content of the diet on the size and appearance of the adrenal in 10 rats which had been subjected to unilateral nephrectomy and which were given injections of crude lyophilized pituitary tissue, crude saline extracts of fresh beef pituitary glands, pituitary adrenocorticotropic hormone, methyltestosterone, sodium thyroxinate and desoxycorticosterone acetate.

The senior author of the monograph has attracted attention by his "general adaptation syndrome," according to which the adrenal cortex is involved in many diseases (rheumatism and hypertension, for example) which he considers to be a result of the stresses of modern life. The simplicity with which this theory explains the phenomena of disease has attracted attention, but the more perspicacious workers in the field have not yet accepted it as fully satisfactory. The present monograph is an example of how wide conclusions may be drawn from a few experiments. Such statements as (page 28) "Since endogenous or exogenous protein-catabolites increase the ability of the pituitary to produce corticotrophin under stress, protein-anabolic testoids may inhibit hypophyseal corticotrophin secretion by diminishing the available supply of endogenous protein-catabolites," may impress some readers but will be criticized by the reader who prefers a simple presentation. Likewise, the morphological changes described in the adrenal do not justify the broad conclusions drawn by the authors.

The printing and format of this text, except for occasional oversights in proofreading, are excellent. Admirers of Selye's work will like the book; his critics will find it wanting.

Cytology of the Human Vagina. By Inés L. C. de Allende, M.D., Chief of the Division of Endocrinology, Mercedes and Martin Ferreyra Institute of Medical Investigation, and Oscar Orías, M.D., Director, Mercedes and Martin Ferreyra Institute of Medical Investigation, Córdoba, Argentina. With a Foreword by Bernardo A. Houssay, M.D. Translated from the Spanish by George W. Corner, M.D. Cloth. $7.50. Pp. 286, with 75 illustrations. Paul B. Hoeber, Inc. (Medical Book Department of Harper & Brothers), 49 E. 33rd St., New York 16, 1950.

Thanks to the brilliant studies of Papanicolaou and others, it is now known that the vaginal mucosa in many animals and in humans reacts to hormones. Therefore, the trophic and cyclic functions of the sex hormones may easily be studied by cytological examination of the vaginal contents. This book is based on such intensive study. The translator is to be congratulated on having produced a book which is delightful to read.

The book is the result of long term study of about 200 examinations of normal subjects and those suffering from disorders of genital function. The authors discuss the female reproductive system, the human vaginal epithelium and its variations, preparations of the vaginal smear, characteristic vaginal smears and cytological curves, cytology of the vagina during the ovulating menstrual cycle, anovulatory cycles as seen in vaginal smears and the correlation between vaginal smears and menstrual disorders, sterility and other conditions.

Some of the clinical conclusions drawn by the authors might be contested. One might take strong issue with the statement that one should regulate the use of estrogens by maintaining the vaginal cornification within physiological limits, and with its characteristic alterations. The patient's clinical response and improvement are more important than the type of vaginal epithelium which follows the administration of estrogens. Not all will agree on the therapeutic use of estrogens in sterility due to ovarian insufficiency as advocated by the authors. It was found that progesterone neutralizes the exaggerated estrogenic activity and brings on menstruation if amenorrhea has existed. The most definite indication for testosterone therapy was found to be quick action in counteracting an exaggeratedly high estrogenic activity in the body. The administration of chorionic gonadotropins alone did not visibly improve the grade of vaginal cornification in cases of ovarian insufficiency. When chorionic gonadotropin was combined with a hypophyseal factor, the effect was to advance by one or two grades the functional capacity that exists at the start of treatment. At the end of the book is an extensive bibliography, which is valuable in itself. There are 75 illustrations, many in color. All the illustrations and charts have been well reproduced; the quality of the paper is good, and the book is well bound. The authors, the translator and the publishers are all to be congratulated on the excellence of the book.

Principles of Public Health Administration. By John J. Hanlon, M.S, M.D., M.P.H., Associate Professor of Public Health Practice, School of Public Health, University of Michigan, Ann Arbor. Cloth. $6. Pp. 506, with 48 illustrations. The C. V. Mosby Company, 3207 Washington Blvd, St. Louis 3, 1950.

The modern health department must do a complex job in a complicated social structure. The health officer must integrate his staff with all its varied training disciplines into a working team; cooperation of members of the health professions in private practice must be obtained; the community must be educated to look after its health needs, and other governmental and voluntary agencies must be understood so the health department program may be suitably integrated into the community picture.

Hanlon's new book gives much emphasis to the health officer's administrative problems, with full discussions of personnel management, fiscal and legal matters, public relations and the basic principles of organization. Public health administration has approached these problems in recent years with the scientific method now becoming widely used in the social sciences, and there is a great wealth of highly useful material. However, no previous public health textbook has devoted this much attention to these matters, even though they occupy a rather large proportion of the day's work.

The usual basic services of vital statistics, communicable disease control, maternal and child health, environmental health, laboratory services and health education are considered adequately. In addition, much attention is devoted to chronic disease control and to the administrative problems of medical care as they affect the health officer. Obviously, with communicable disease control as advanced as it now is, the community requires measures to aid in solving the chronic disease problems which are now the major public enemies. There exist already technics, such as multiphasic screening, which can best be applied on a community basis and which hold real promise of worth while achievement in aiding in the control of this group of diseases. The book contains a most interesting discussion of the economic and social value of preventive medicine, with much more detailed treatment than is usually found.

Unfortunately, insufficient emphasis is given to problems of such importance as mental health, nutrition, accident prevention, alcoholism, the hygiene of housing and disaster services. The health department of today must prepare itself to discharge its proper role in these fields also. Little attention is paid to the place of the medical social worker in public health activities, and the discussion of health centers is much too brief to be satisfactory. There is inadequate consideration of the essential planning roles of health councils and similar bodies so important in giving the citizen the chance to play the part in the total health program which only he can play. The bibliography is mediocre, and the indexing could definitely be improved to make the wealth of subject matter more readily available.

Even with these limitations, the book is still an unusually valuable one and represents a definite step forward in providing a textbook for public health students and a manual for active workers in the field. The practicing physician who is a member of a board of health or is active in community health services will find much helpful information also. It is primarily for "the man who decides to devote his professional life to . . . public health administration. What is expected of him appears to be impossible. Physician, engineer, lawyer, political scientist, economist, sociologist—must he be all of these and more?" The answer is, of course, in the affirmative, and this book will make the impossible task even more satisfying and rewarding than it now is.

Eyes and Industry (Formerly Industrial Ophthalmology). By Hedwig S. Kuhn, M.D. Second edition. Cloth. $8.50. Pp. 378, with 151 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1950.

In this edition, this well known textbook on industrial ophthalmology retains its authoritative preeminence in the field. It contains much of importance not only to the industrial surgeon and the ophthalmologist with a primary interest in the field but also to the ophthalmologist who may see as private patients persons whose condition of work may play an important role in ocular comfort and efficiency.

There is a discussion of the technics of visual testing in industry, visual skills in relation to the type of employment, visual standards and the possibilities of a corrective program. A special chapter on eye injuries caused by solid bodies is contributed by Dr. Albert C. Snell and should prove informative, especially to those charged with emergency treatment of eye injuries. Further chapters deal with damage from radiation and chemicals, types of protective goggles, illumination in industry and the place of the blind in industry. In a miscellaneous chapter is discussed monocular cataract and epidemic keratoconjunctivitis in what may seem a rather illogical grouping of two unrelated conditions. Conveniently included in the appendix are the report of the Committee on Compensation for Eye Injuries of the American Medical Association, the federal specifications for goggles, standing orders for nurses and miscellaneous information on fluorescent lighting, tinted lenses and other material quoted from a number of sources.

Bronchoscopy in Pulmonary Tuberculosis: A Clinical Study of 1,001 Cases of Bronchoscopic Examinations. By Nils Froste. Acta tuberculosea scandinavica, supplementum XXIII. Paper. Pp. 119, with 2 illustrations. Boden; Ejnar Munksgaard, Nørregade 6, Copenhagen K, 1950.

The author is the consulting bronchoscopist at the Central Sanatorium in Sandträsk. The book is divided into chapters covering the following subjects: historical survey, material, technic, nomenclature and consultation procedure, indications and contraindications, lymphadenitis, tuberculosis, bronchostenoses, valve mechanism, atelectasis, hemoptysis, occlusion and aspiration treatments, routine bronchoscopy and postbronchoscopic complications.

Following a review of historical data, the author points out that at present there is a definite increase in the use of bronchoscopy for diagnosis in diseases of the lung. However, the therapeutic work with bronchoscopy has suffered a setback since the introduction of paraaminosalicylic acid and streptomycin for the treatment of bronchial complications in pulmonary tuberculosis.

Much space is devoted to the subject of biopsy in tuberculosis, and a special investigation was carried out to determine whether such a procedure on the bronchomucous membrane produced any "inconvenience." Of eight cases in which results of biopsy were positive for tuberculosis, there was progression in two after biopsy. In one case, in which results of biopsy were negative, bronchogenous extension of the tuberculosis arose. The author emphasizes that these three cases should at least suggest a warning note as to the possible dangers of the procedure. At the end of the book a rather inclusive bibliography is found. The book is easily read, and many illustrative cases are presented. It can be recommended to anyone interested in the bronchoscopic phase of pulmonary tuberculosis.

Surgical Treatment for Abnormalities of the Heart and Great Vessels. By Robert E. Gross, M.D., William E. Ladd Professor of Child Surgery, Harvard University Medical School, Boston. The Beaumont Lecture, Wayne County Medical Society, Detroit, Michigan. Publication Number 3, American Lecture Series, A Monograph in American Lectures in Surgery. Edited by Michael E. DeBakey, M.D., Associate Professor of Surgery, Tulane University, New Orleans, and R. Glen Spurling, M.D., Clinical Professor of Surgery, University of Louisville, Louisville, Ky. Thoracic Surgery Division, Editor: Brian Blades, M.D., Professor of Surgery, George Washington University, Washington, D. C. Second printing. Cloth. $2. Pp. 72, with 36 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This is the twenty-fifth Beaumont Lecture, delivered in 1946 and first published in monograph form in 1947. The author was a pioneer in the development of operations for correction of most of the conditions described, which include patent ductus arteriosus, defects of the pericardium, the tetralogy of Fallot, anomalies of the aortic arch and subclavian artery and coarctation of the aorta. When the monograph was written, the author had operated on 130 patients with patent ductus arteriosus and seven patients with coarctation of the aorta. Although his operative experience has since been greatly extended, the views expressed are essentially the same as those in his more recent publications. The pathological physiology of the various anomalies is thoroughly discussed, and surgical technics are clearly illustrated.

The National Formulary. Ninth Edition. National Formulary IX. Prepared by the Committee on National Formulary under the supervision of the Council by the Authority of the American Pharmaceutical Association. Official from November 1, 1950. Cloth. $8. Pp. 877. American Pharmaceutical Association, 2215 Constitution Ave., N.W., Washington 7, D. C.; Mack Printing Company, Easton, Pa., 1950.

The new formulary contains titles and standards for 155 articles not previously included. A total of 162 items official in the previous edition were not admitted to this edition. As has been customary in the past, the admission of drugs to this edition is based not only on the therapeutic value of a given agent but also on the extent of its use. The trend to abandon outmoded botanicals and biologic preparations, which received impetus in the previous edition, is continued. Representative of this type of deletion are the botanicals uva ursi and valerian and animal products of questionable therapeutic value, such as ovary and anterior pituitary. Individual specifications for previously official drugs have also been revised and improved. Among the new features of this edition are specifications for disintegration time for tablets, weight variation standards for tablets and requirements limiting weight variation in the contents of dry ampuls and other containers. The general chapter on injections has also been revised. The new National Formulary reflects the basic changes in drug therapy which have evolved in recent years. It has value to pharmacists and pharmaceutical manufacturers as a source for information and standards for certain drugs and also provides physicians with an "official" list of many popular therapeutic agents.

Las formas anatomoclinicas de la tuberculosis tráqueobronquial en sus relaciones con la tuberculosis pulmonar del niño y del adulto. Por el doctor Manuel Tapia. Con la colaboración de los doctores José Manuel Soares de Oliveira y Luis Cerezo. Con un capitulo sobre la técnica de la broncoscopia. Por el doctor Antonio da Costa Quinta, otorrinolaringólogo del Hospital infantil de San Roque, de Lisboa. Cloth. 390 pesetas. Pp. 718, with 516 illustrations. Editorial Alhambra, Mayor, 4, Madrid, 1950.

This excellently prepared volume in Spanish on tracheobronchial tuberculosis covers a significant phase of pulmonary tuberculosis in a detailed and exhaustive fashion, adequately illustrated by colors, diagrams and photographs. The text displays a good knowledge of the subject as a result of long experience in the work concerned. The volume details the arboral bronchial distribution and limitations concerning the pulmonary segments and presents the various advances and views on this subject. Tuberculous tracheobronchitis is considered generally as to frequency and anatomic, pathological and pathogenic characteristics in relation to the primary infection and subsequent reinfection and exacerbations. The importance of tuberculosis of the bronchi and difficulties in diagnosis with the syndromes of extension in the chronic forms are detailed. Radiological diagnosis, including indirect signs, and bronchography are well covered. Classification as to type of tuberculoses and the relation of adenopathy to this are viewed liberally, even to the consideration of perforation. The forms of extension are completely elucidated, and treatment in all phases is covered, including rest, climate, symptomatology, ultraviolet rays, cauterization, antibiotics and paraaminosalicylic acid. Collapse treatment is discussed, and full consideration is accorded pneumothorax, thoracoplasty, phrenicectomy and pneumoperitoneum. A chapter is devoted to resection (pneumonectomy and lobectomy), and in a final chapter the technic of bronchoscopy, with preparation, anesthesia and difficulties encountered, is described.

This well presented volume is liberally illustrated, detailed in every respect and printed on a high grade, filled paper. It can be recommended particularly to physicians conversant with Spanish who are interested in tracheobronchial conditions and tuberculosis in particular.

Psychiatry for Social Workers. By Lawson G. Lowrey, M.D. Second edition. Cloth. $4.50. Pp. 385. Columbia University Press, 2960 Broadway, New York 27, 1950.

This book has been prepared as a guide to social workers to *enable them to recognize symptoms of common psychiatric dis*orders which may underlie the maladjustments of the persons with whom they deal in case work. It provides useful information for the social worker in deciding when he should call for psychiatric diagnosis and treatment, and it contains information which will enable him to realize the limitations of nonprofessonal treatment. Data on etiology, psychopathology, history, prognosis and treatment are provided for the major types of disorders. In this edition, many of the chapters have been completely revised, and a chapter on the social worker and treatment has been added which outlines some of the basic principles of case work treatment and psychotherapy. The responsibilities that a social worker may assume in treatment have been clearly defined.

Immortal Magyar: Semmelweis, Conqueror of Childbed Fever. By Frank G. Slaughter, M.D. Cloth. $3.50. Pp. 211, with 5 illustrations. Henry Schuman, Inc., Publishers, 20 E. 70th St., New York 21, 1950.

This excellent story of the life of Semmelweis appears shortly after another well written dramatization of one of the world's greatest benefactors ("The Cry and the Covenant"). The author of this book presents the tragic life of Semmelweis in a most interesting fashion. His data are factual, and he quotes fairly extensively from Semmelweis' own book, "Die Aetiologie, der Begriff and die Prophylaxis des Kindbettfieber." Slaughter is to be commended for having again brought to everyone's attention what a true scientist Semmelweis was and how his life ended in a great tragedy as a martyr to the world's stupidity. This book is definitely worth reading, even though its subject matter constantly upsets the reader because of "man's inhumanity to man."

On Low-Back Pain with Special Reference to the Value of Operative Treatment with Fusion: A Clinical and Experimental Study. By Lars Unander-Scharin. Acta orthopaedica scandinavica, Supplementum no. V. Translated from Swedish by Captain Jack O'Brien-Hitching, M.C. Paper. Pp. 221, with illustrations. Ejnar Munksgaard Forlag, Nørregade 6, Copenhagen K, 1950.

This book is divided into eight chapters: anatomy, physiology, pathology and pathophysiology of the interverbral disk; previous investigations of the roentgenologic picture, connection with trauma and the value of conservative treatment in lumbar disk degeneration; frequency of lumbago and sciatica among the members of the Stockholm Sick Benefit Society and the employees of the Stockholm Tramway Company; results of cases of lumbago and/or sciatica with roentgenologic disk degeneration that have been treated conservatively or left untreated; surgical treatment of disk degeneration in the lumbosacral spine; analysis of 80 patients with lumbar disk degeneration treated by spinal fusion; discussion of the clinical material, and investigations of the pressure conditions in the lumbar intervertebral disks with regard to the effect of lumbar osteosynthesis.

In chapter 2 the author quotes the work of Friberg and *Hirsch (1949). One hundred spines were removed from post*mortem specimens; these were radiographed in flexion and extension. It was found that pronounced degenerative changes were present without any radiographic manifestations. In cases where instability was present there were also conspicuous changes in the disk. When the roentgenogram revealed reduced disk space, sclerosis or osteophytes, the corresponding disk was severely damaged. The author believes that this investigation gives strong support to the opinion that lumbago and sciatica have their origin in degenerative changes in the intervertebral disks.

Among 6,948 male employees of the Stockholm Tramway Company, 408 were given diagnoses of lumbago and/or sciatica. It is thought probable that some connection exists between this high frequency of lumbago and/or sciatica and the nature of the work of the traffic staff. Of 185 men and 245 women treated in the hospital, 21 men and 18 women were operated on. The results of surgical treatment have been better than those obtained from conservative therapy, despite the fact that the patients treated surgically were those with the more serious conditions. The book consists of the compilation of a great deal of *statistical* data and should make a good reference volume for anyone interested in the subject of low back pain.

The Pathogenesis and Pathology of Viral Diseases. Edited by John G. Kidd. Symposium held at the New York Academy of Medicine, December 14 and 15, 1948. Symposia of the Section on Microbiology, The New York Academy of Medicine, Number 3. Cloth. $5. Pp. 235, with illustrations. Columbia University Press, 2960 Broadway, New York 27, 1950.

Since the organization, in 1947, of the Section on Microbiology of the New York Academy of Medicine, important contributions to modern medical literature have been made by that group. This, the third volume of a series of published symposia on bacterial, fungus and viral diseases, represents 14 papers presented on this subject. Many phases of the study of viruses are included. Dissemination of viruses, their relation to tissue cells, the lesions produced by several viruses and the pathological changes inherent therein are among the subjects presented. The bibliography supplied for each chapter enhances the value of the volume, and the book is recommended to those interested in the advances in virology.

Light Therapy. By Richard Kovacs, M.D., Professor of Physical Medicine, New York Polyclinic Medical School and Hospital, New York. Publication Number 57, American Lecture Series, A Monograph in American Lectures in Physical Medicine, edited by W. A. Selle, Ph.D., Professor of Biophysics, University of California School of Medicine, Los Angeles. Cloth. $2.25. Pp. 112, with 28 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 49 Broad St., Oxford, England; The Ryerson Press, 299 Queen St., W., Toronto 2B, 1950.

This brief and attractive book is a semipopular sketch of the uses to which ultraviolet, visible and infra-red radiation have been put at various times in the treatment of human disease. It contains much scientific information and illustrates some recent forms of physical therapeutic apparatus, but it also contains some misleading statements, together with numerous small errors that are likely to puzzle students. It can be recommended, however, to physiatrists interested in having a recent summary of knowledge and attitudes in this particular *field.*

Textbook of Abnormal Psychology. By Roy M. Dorcus, Professor of Psychology, University of California, Los Angeles, and G. Wilson Shaffer, Dean of the University, Johns Hopkins University, Baltimore, Maryland. Fourth edition. Cloth. $5. Pp. 717, with illustrations. The Williams & Wilkins Company, Mount Royal & Guilford Aves., Baltimore 2, 1950.

This highly successful, now standard, textbook of abnormal psychology has reached this edition with little fundamental revision. The book is not truly a textbook of abnormal psychology, for it contains much of basic neurology and physiology. It attempts an encyclopedic, unbiased attitude toward every field and endeavor which can be considered significant to the understanding of abnormal psychology. As a result, it has a certain attractiveness for the academic teacher and lacks the emphasis on living human beings with problems of adjustment that the serious student of abnormal psychology needs. It has an extensive glossary, detailed author and subject indexes and 12,000 *bibliographic references.*

QUERIES AND MINOR NOTES

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

FAMILIAL DEAFNESS

To the Editor:—Two healthy young persons of good family background have three children. The older daughter, aged 8, and the only son, aged 2, are congenitally deaf. The daughter also has frequent bouts of pyuria with fever. No anomaly of the urinary tract has been found, despite adequate studies in two excellent institutions. The younger daughter, aged 6, has an interventricular septal defect. The younger brother of the father of these children and the younger sister of the mother have decided to marry. I was asked about the chance of the younger pair's having children with congenital defects. It is my guess that the father and mother of my patients each has a recessive gene which, combined, leads to defective offspring. Could you tell me where I could find an authoritative opinion? Hedwig Koenig, M.D., New York.

ANSWER.—Making the reasonable assumption that the deafness in this family is due to a recessive gene and that only one of the grandparents carried this recessive gene, one may state that the chance of the father's brother carrying the gene is one half. The chance of the mother's sister carrying the gene is also one half. The chance that both of these people carry the same recessive gene is therefore one quarter. If this chance is fulfilled, they may have some deaf children. The chance of any child's being deaf, if both parents carry the recessive gene, is one quarter. This makes the over-all probability of one sixteenth that a child of this marriage would be deaf.

TRICHOMONAS URETHRITIS

To the Editor:—What is the best treatment for a man, aged 51, with urethritis due to Trichomonas? An associated prostatitis exists, and a subsequent smear after vigorous prostatic massage revealed many pus cells and some Staphylococcus albus and diphtheroids. Sensitivity tests show penicillin to be the drug of choice, and I have given him 1.5 cc. of procaine penicillin in oil (300,000 units per cubic centimeter) daily for six days. He no longer has urethral discharge. However, arthralgia developed, and he complains of pains in the wrists, one ankle and one heel on awakening. These pains disappear by noon. Of what significance are these pains? Would aureomycin help? How soon may prostatic massages be resumed, and how often? M.D., Illinois.

ANSWER.—In most cases, chronic or subacute urethritis, whether due to Trichomonas or other agents, is secondary to prostatitis or urethral stricture and may be expected to disappear spontaneously after proper treatment of the underlying condition. The development of arthralgia raises the question of Reiter's syndrome, in which case dihydrostreptomycin would be the drug of choice. Locally, prostatic massage should be continued weekly until the prostatic fluid shows only 5 to 8 white cells per high power field on a thin wet smear. Heat in the form of rectal irrigations or hot sitz baths are beneficial as well as general hygienic measures. Before therapy is concluded, the possibility of a large-caliber stricture should be eliminated by calibration of the urethra with a bulbous bougie.

AIR HUNGER

To the Editor:—A patient complains of air hunger, more pronounced in the evening or when she becomes tired. No other symptoms are present. She has borderline anemia, for which I administer mety-carsiron (a proprietary mixture of iron, copper and sodium cacodylates) and thiamine hydrochloride intravenously daily, with no effect. The only way she can gain relief from air hunger is by yawning. What could be the cause of this, and what treatment do you suggest?
Forrest C. Lawrence, M.D., Bartlesville, Okla.

ANSWER.—It is assumed that the important causes of air hunger have been ruled out, for example, heart failure, nephritis, diabetes, pulmonary fibrosis, emphysema, tumor, congenital anomalies of the heart or lungs and other causes of anoxia. The patient should be examined for "borderline" anemia; if anemia is present, proper therapy, depending on the type of anemia found, should be instituted. If, as stated, no other symptoms, and presumably no abnormal signs, are present and if one yawn immediately stops the air hunger, the condition perhaps represents a neurosis. If air hunger recurs after the few normal respiratory cycles, another underlying cause must be sought, some of which are named above. If the patient is neurotic, reassurance and deep breathing exercises may be helpful. The underlying cause of the neurosis must be sought and corrected.

TREATMENT OF MULTIPLE SCLEROSIS

To the Editor:—An article on multiple sclerosis appears in the December 1950 issue of *McCall's* magazine. I have been asked many times about this article and the advisability of Dr. Hinton Jonez' treatment at St. Joseph's Hospital, Tacoma, Wash. Any information you may give will be appreciated. Frank J. Burian, M.D., Williamson, W. Va.

ANSWER.—The course of treatment given by Dr. Hinton D. Jonez is purely for the relief of symptoms of multiple sclerosis. It seems to combine the work done by other investigators with emphasis on possible allergic factors. The histamine therapy was tried some years ago at the Mayo Clinic, with equivocal results. Curare (and its derivatives) was carefully investigated by Schlesinger and others and is still in use by some as a muscle relaxant. Allergy studies have likewise been carried out elsewhere. Physical therapy and rehabilitative methods are being utilized in several places. Dr. Jonez is using a combination of these methods in the widest concentrated attack on the symptoms of this disease.

The National Multiple Sclerosis Society (270 Park Avenue, New York 17) is convinced of Dr. Jonez' interest in the problem and of his integrity as a physician and scientist. In the absence of any more specific approach either to symptomatic relief of multiple sclerosis or to a cure, Dr. Jonez' program has much to recommend it and is well within the realm of ethical medicine. Neither he nor the society considers that his method cures multiple sclerosis. Further intensive investigation is under way.

Before a patient plans traveling long distances for treatment, inquiry should first be made as to whether such treatment is available through his own physician or medical center in his own or in nearby communities. Dr. Jonez has expressed his willingness to explain his methods to other physicians and is planning to publish his observations. The National Multiple Sclerosis Society strongly recommends that a patient ascertain whether he can be accommodated at Dr. Jonez' clinic before going to Tacoma.

CERVICAL SYMPATHETIC BLOCK AFTER CEREBRAL THROMBOSIS

To the Editor:—Kindly comment on the article in the November 11 issue of the *Saturday Evening Post*, on "something new about strokes."
Eugene F. Wahl, M.D., Edwardsville, Ill.

To the Editor:—A woman, 46 years old, with hypertension had a cerebral hemorrhage in 1945, at which time she lost her speech and was paralyzed on her right side. The patient's right arm now is semiparalyzed, and her right ankle is weak and turned inward. She wears a brace on this leg. The patient read an article in the Nov. 11, 1950, *Saturday Evening Post* that mentions a French surgeon, René Leriche, who is performing stellate ganglion block with procaine solution. It was stated that no danger is involved in this treatment. The patient wishes to try this therapy and has asked my opinion. Please inform me whether there have been any valuable results? Max M. Krauss, M.D., New York.

ANSWER.—A cervical sympathetic block (not a stellate block, which is hazardous in the hands of the average physician) is an easy procedure frequently used in vascular clinics. When this procedure is done within the first six to 12 hours after the occurrence of cerebral embolism or cerebral thrombosis, an acceleration of spontaneous recovery takes place. Obviously, the area of infarction itself cannot be influenced, but the marginal edema and vascular stasis can, since sudden improvement after procaine block of the cervical sympathetics does take place in over 50 per cent of the cases. All workers in this field would agree that cerebral hemorrhage should be excluded from this treatment. If the author had emphasized in his article in the *Saturday Evening Post* that every patient with apoplexy should have a spinal puncture on admission to the hospital, he would have made a large contribution to the welfare of these patients. It is a fact, however, that outside of neurological or neurosurgical clinics spinal puncture is not often carried out. Surgical intervention is definitely and urgently indicated in subarachnoid hemorrhage, and intracerebral hemorrhage can be evacuated in well selected cases, but nerve block cannot mitigate hemorrhage—it may even increase it.

Cervical sympathetic block following apoplexy, in which hemorrhage can be reasonably excluded, is a valuable emergency procedure (J. A. M. A. 136:659-664 [1948]). The article in the *Saturday Evening Post,* however, emphasizes the effect of repeated blocks or sympathectomies in advanced cases and here relies heavily on a California report (*Arch. Surg.* 61:286 [Aug.] 1950). This part of the problem is still in the experimental stage. The mechanism of relief in the advanced cases is unclear, and the value of the procedure is highly debatable.

TREATMENT OF OSTEOPOROSIS

To the Editor:—May I have the latest information on the treatment of osteoporosis in a lower leg after healed fracture with impaired circulation to the foot? The patient is a woman of 40 years. Her blood calcium is 9.5 mg. per 100 cc., and she has a basal metabolic rate of —8 per cent. She takes 2 grains (0.12 Gm.) of thyroid a day.

H. M. F. Behneman, M.D., Palm Springs, Calif.

ANSWER.—Localized osteoporosis usually is due not to any metabolic or endocrine disturbance but rather to a localized disease process, oftentimes with traumatic causation, which results in disturbed circulation to the part and in partial or complete immobilization. Fracture is a common cause, especially if prolonged immobilization in a cast and non-weight-bearing are required. From the meager information supplied, it is assumed that these circumstances reasonably obtained in the case in question and that the fracture was recent. The normal blood calcium substantiates the absence of metabolic fault; the apparent hypothyroid state (controlled by thyroid medication) is not pertinent to the localized osteoporosis. Since the bone decalcification is due to a local lesion, treatment should be essentially local. Measures to normalize circulation should be emphasized. Use of massage, exercises, contrast baths and passive vascular exercises (Buerger's exercises) should be of value. The most important single factor is the establishment of as nearly normal weight bearing on this extremity as is possible, as soon as possible. This will serve more than anything else to normalize function and metabolism in the affected bone.

Usually measures of benefit for generalized decalcification are of little or no help (high protein diet with androgen or estrogen therapy). Recovery of normal or nearly normal bone usually results if the management can be successfully instituted, although recalcification is notoriously slow.

Rh NEGATIVE WIFE, Rh POSITIVE HUSBAND

To the Editor:—I would appreciate advice on the following case: The wife's blood is group O, Rh negative, and the husband's, group O, homozygous, Rh positive (type Rh_1Rh_2 [CDe/cDe]). The only child is group O, Rh positive (type Rh_2 [cDE/cde]). The second pregnancy proceeded normally, antibodies developing in low titer at the twenty-sixth week. The titer gradually rose until the thirty-fifth week, when it was 1:512 in serum albumin. No blocking antibodies ever developed. At the thirty-sixth week the titer doubled, but labor was not induced. A few days later the child died in utero. The patient has been told that in all future pregnancies the child may die in utero or, if born alive, will require exsanguination-transfusion. If this is correct, can anything be done to prevent an antibody response? Is hapten of any use? Can it be obtained? Does the administration of vitamin K and progesterone throughout pregnancy prevent the passage of antibodies through the placenta? If treatment will not prevent fetal damage, should the patient be allowed to become pregnant again?

V. N. Gordon, M.B., Ch.B., South Africa.

ANSWER.—The husband is Rh positive and almost surely homozygous, while the wife is Rh negative and strongly sensitized to the Rh factor. Under such conditions, every child will almost surely be Rh positive and therefore severely erythroblastotic; in fact, it is very likely that every fetus will be stillborn. Only in exceptional cases will a viable erythroblastotic baby be born that can be saved by multiple transfusions of Rh-negative blood or by exchange transfusion (East, E. N., and Mair, C. M.: Intensive Immunization of an Already Sensitized Rh-negative Woman: Birth of a Mildly Diseased Baby, *J. Lab. & Clin. Med.* 34:983 [July] 1949). With regard to the reference cited, it should be pointed out that the title of the article is misleading, because the clinical course indi[illegible] that the baby was severely affected and was lucky to have [illegible] It was only after nine transfusions of a total of 560 [illegible] over [illegible]riod of 10 weeks that this baby finally re[illegible]

The couple may decide that, [illegible]ss, they wish to try again. A still[illegible]vitable, but by inducing labor fo[illegible] one might succeed in c[illegible] a [illegible] to practice contra[illegible] therapeutic abortio[illegible] justifiable, because such a pregnancy is almost certain to terminate with a hydropic stillbirth, and such stillbirths are associated with increased danger to the mother from toxemia and postpartum hemorrhage. If the patient becomes pregnant a second time, sterilization of the patient or her husband should be broached. If the couple is very anxious to have another child, they could adopt one, except that, in general, adoption agencies tend to give priority to childless couples. If the temperament of the couple is suitable, artificial insemination from an Rh-negative donor may be resorted to; this has never failed. However, one must bear in mind the moral and legal implications of the procedure (McCurdy, R. N. C.: The Rhesus Danger—Its Medical, Moral, and Legal Aspects, London, Wm. Heinemann Medical Books, Ltd., 1950). At least one court has found Rh sensitization grounds for divorce, maintaining that husband and wife are not sterile and could have children with other spouses of compatible Rh type.

Once a patient has become sensitized to the Rh factor, nothing can be done to eliminate or reduce the Rh antibody titer. The so-called Rh hapten has proved inert both in vitro and in vivo and is not recommended for treatment (Unger, L. J.: Studies on Preventive and Curative Treatments for Rh Sensitization, *Am. J. Obst. & Gynec.* 58:1186 [Dec.] 1949). Univalent Rh antibodies which are responsible for the disease, readily pass through the placenta, and vitamin K, progesterone and other drugs cannot prevent the placental transfer of antibodies (Wiener, A. S.: Rh Factor in Immunological Reactions, *Ann Allergy* 6:293 [May-June] 1948).

PROCAINE PENICILLIN AND SULFONAMIDES

To the Editor:—There have been reports that the procaine base part of the procaine penicillin preparations has an inhibitive action on sulfonamides, that the procaine part of a 1 cc. dose was enough to make concomitant sulfonamide therapy impossible. Is this correct? Can penicillin be expected to be stable for any length of time in a 3 per cent aqueous solution of sodium bicarbonate?

R. J. Kent, M.D., Savannah, N. Y.

ANSWER.—Procaine penicillin preparations contain about 120 to 125 mg. of procaine to each 300,000 units of penicillin per milliliter. Woods has demonstrated that a small quantity of paraaminobenzoic acid interferes with the effects of sulfanilamide and sulfapyridine and that procaine had a similar but delayed effect. This delay is probably due to the time involved in the enzymatic hydrolysis of procaine to paraaminobenzoic acid. In vitro studies show that paraaminobenzoic acid must be present only in a ratio of 1:2,000 to inhibit sulfanilamide but a concentration of 1:70 is necessary to inhibit sulfathiazole and the more soluble sulfonamides, such as sulfadiazine and sulfacetamide.

Studies in man indicate that after an injection of 1,500,000 units of aqueous procaine penicillin, appreciable levels of free procaine or paraaminobenzoic acid could not be demonstrated in the blood stream of over half the subjects tested, but evidence of an acetylated derivative of paraaminobenzoic acid was found. In 30 per cent of those tested, concentrations of less than 0.1 mg. of paraaminobenzoic acid per milliliter of serum were found, and 20 per cent showed insignificant traces of procaine.

Both the procaine and the acetylated paraaminobenzoic acid may be disregarded for inhibitory effect since the former is present in too low a concentration and the latter is relatively inactive. However, in the doses administered 30 per cent of the subjects tested did have blood concentrations of paraaminobenzoic acid sufficient to theoretically inhibit the action of sulfanilamide and sulfapyridine, but not sulfathiazole, sulfadiazine and other more soluble sulfonamides.

The procaine from procaine penicillin is released slowly, which probably accounts for the failure to attain a significant blood level of procaine. In addition, the paraaminobenzoic acid formed is excreted with relative rapidity. Therefore, the low total amount of procaine in procaine penicillin preparations, as well as its slow rate of release into the blood stream, and the rapid rate of excretion of paraaminobenzoic acid would make negligible any inhibitory effect of procaine penicillin preparations on the more soluble sulfonamides.

The stability of solutions of unbuffered sodium penicillin G kept at room temperature is rather short; within two days more than half of the original potency is lost. When kept at 10 C. and when a 0.1 M citrate buffering system was used, little appreciable loss was noted after 40 days, with but 20 per cent loss of potency after 80 days. Sodium bicarbonate would have slight preservati[illegible] action, since the products of penicillin decomposition are [illegible] but the stability would be only slightly longer than for [illegible]fered solutions.

CHEMICALS USED IN TANNING LEATHER AND IN SHOE POLISH

To the Editor:—What kind of chemicals are used in tanning leather for tan and black shoes, and what chemicals are used in the material for polishing both types of shoes? Is is possible to absorb any of this material? What effect would one experience?

Lester V. Stallsmith, Ph.D., Wilkes-Barre, Pa.

Answer.—Leather intended for black and for tan shoes undergoes the same early treatment. Such leather may represent the full thickness of some skins, such as calf skin, or a split of thicker hides, such as from cows. Preparation prior to tanning involves many steps and many chemicals. Among other chemicals are lime, sulfites, mineral and organic acids, amines and enzymes.. Tanning may be accomplished with a variety of agents, including chrome, aldehydes, quinones and vegetable and synthetic tannins. Tanning is followed by oiling and softening and at times splitting and artificial graining. In due course some leathers are dyed, otherwise colored or enameled. Paraphenylendiamine used to be extensively employed but has largely disappeared. Earlier, too, common solvents included the dangerous benzene methanol and nitrobenzene. Now various other alcohols, esters and naphthas are used. The choice of coloring agents is wide, but aniline dyes in black and brown are mostly used. Despite the protean steps and agents involved, good leather as made into shoes is without significant danger to the prospective wearer. Rarely on a basis of allergy skin affections may arise.

The formula for black shoe polishes is typical: 5 parts montan wax, 15 parts ceresin wax, 5 parts beeswax, 2 parts oil-soluble nigrosin and 50 parts turpentine. For tan polishes the same formula but without the coloring agent may be used, or low quantities of brown dyes may be introduced. Substantially no danger derives from their use. There is enormous variation in polish and dye constituents, and some brands may contain harmful agents.

SLIGHT PTOSIS OF UPPER EYELID

To the Editor:—A 14 year old girl has had slight blepharoptosis of the left eye since the age of 7. Some days it is slight; some days it is more noticeable. The girl is otherwise normal. I wish to know the possibility of a nonsurgical treatment, particularly the action of neostigmine, and the relation of this disorder to generalized myopathies.

Manuel Besoain-Santander, M.D., Santiago, Chile.

Answer.—Since there is no other abnormality and ptosis has been present for seven years with some variation in degree, the two most important diagnoses to consider are myasthenia gravis and progressive nuclear ophthalmoplegia. To differentiate between the two, a diagnostic injection of 1.5 mg. of neostigmine combined with 0.6 mg. of atropine should be given. A positive response of disappearance of the ptosis will favor a diagnosis of myasthenia gravis. The ptosis of progressive nuclear ophthalmoplegia will not respond to neostigmine. In this disease, ptosis often is the first symptom; it may be unilateral or bilateral and may be present for a number of years before the extraocular muscles are affected. The disease is progressive and the extraocular muscles eventually will become affected. Also, strong hereditary factors are involved, so that a careful search of the family history should be made. Progressive nuclear ophthalmoplegia may be seen in certain types of progressive muscular atrophy, but rarely with amyotrophic lateral sclerosis. It is observed also with tumors or vascular lesions of the brain stem, in multiple sclerosis, tabes, dementia paralytica, intoxication from lead, botulism, Wernicke's disease, and as a result of injuries. So far as nonsurgical treatment is concerned, the use of the "crutch" glass is probably the best device available. Neostigmine would be of value only if a diagnosis of myasthenia gravis is made.

NEW GROWTHS IN BREASTS OF INFANTS

To the Editor:—A 9 month girl has a firm, movable, discoid, nontender, subcutaneous mass, about 2.5 cm. in diameter, in the left breast. The center of the mass corresponds to the nipple but does not appear to be attached to the skin. Moderate prominence of the breast is obvious. The mass has been present since the child was 1 month old and appears to have grown slightly in recent weeks. I have observed this child almost daily, and she appears to be in perfect health. I would appreciate a brief discussion of the differential diagnosis.

M.D., Canal Zone.

Answer.—New growths of the infant breast are extremely uncommon. They are uniformly benign. Among those that have been observed are dermoid cyst, hemangioma and a rare intraductal papilloma with bleeding from the nipple. The single case of intraductal papilloma presented a soft, centrally located swelling. Pressure about the nipple produced a bloody discharge from the nipple.

These must be clinically differentiated from the common mastitis neonatorum which may appear immediately or shortly after birth and persist for a variable time. Occasionally this may be unilateral and persist for several months. As a rule, a flat, diffuse and slightly nodular swelling is palpable beneath the nipple and areola. No treatment is necessary, since the condition subsides spontaneously.

A cyst is palpable as a well defined and rounded mass located about the margin of the areola. Hemangiomas are more prone to appear in the parenchyma of the breast. They occur as soft, compressible and diffuse swellings. When deeply located and cavernous in type, there is only a faint, if any, bluish discoloration of the overlying skin.

LATENT SYPHILIS OR FALSE POSITIVE REACTION?

To the Editor:—A 42 year old woman had a 2 plus Kahn reaction of the blood in 1942. In September 1949 the state health department reported the following reactions: blood Kline, Wassermann and Kolmer positive and blood Kahn doubtful. A private laboratory reported the Kahn blood reaction positive at the same time, and another private laboratory gave the following results of blood tests: quantitative 10 units and Kahn, Kline, Mazzini and Pangborn reactions strongly positive. The spinal fluid in 1949 was clear and colorless, with 1 white blood cell, 1 lymphocyte, negative Pandy reaction, total proteins 100 mg., negative Kahn reaction, gum mastic 000000 and negative Kolmer reaction. Results of Kahn and Kline tests of the blood were positive, quantitative 4 units, Kolmer negative and Kline cardiolipin positive. A blood Kahn reaction of the blood was reported positive in July 1950, with 4 quantitative units. This patient denied having had venereal disease or having been treated for it. Results of her physical examination are normal. She had the usual childhood diseases and scarlet fever, asthma and eczema. In 1938 her tonsils and adenoids were removed; in 1942 she underwent a right nephrectomy and in 1949 an appendectomy. Does this patient have syphilis? Does the protein level indicate neurosyphilis? What treatment would you suggest?

M.D., Ohio.

Answer.—This patient has either late latent syphilis or a biologic false positive serologic reaction for syphilis. One cannot say which diagnosis is correct on the basis of standard serologic tests for syphilis. The abnormally high spinal fluid protein suggests central nervous system disease. It is unlikely that this disease is syphilis because of the negative spinal fluid complement fixation. This disease, whatever it may be, might be responsible for the false positive blood reaction. If, on repeated examination, the spinal fluid protein is still abnormally high and no cause can be found, then antisyphilitic treatment may be given. Treatment is given only because a definite diagnosis cannot be made and to give the patient maximum protection for the future in case she does have syphilis. A total of 6,000,000 units of procaine penicillin in oil with 2 per cent aluminum monostearate, given in 10 doses over a period of two to three weeks, should be adequate therapy.

RETARDED GROWTH

To the Editor:—A 7 year old girl, weight 30 pounds (14 Kg.), height 37¼ inches (95 cm.), has a normal history, with the usual childhood diseases. She has a poor appetite, desiring primarily carbohydrates, and takes about two hours to finish her meal. Her intelligence quotient is above average. Physical examination discloses no abnormalities. The parents are 5 feet 7 inches (170 cm.) and three other children are normal in height and weight. This girl has grown 1 inch (2.5 cm.) and has gained about 4 pounds (2 Kg.) in the past year. The parents are apprehensive concerning the weight and growth of this girl.

C. L. Qualls, M.D., Beaver Dam, Wis.

Answer.—Heredity and environment apparently do not play a role in this instance, as the parents and other siblings are normal. Although the physical examination disclosed no abnormalities, certain congenital defects may be discovered only by intensive studies. Congenital cardiovascular genitourinary and gastrointestinal hidden defects may stunt growth and development. Consequently roentgenograms of the chest, electrocardiograms, blood chemistry determinations (nonprotein nitrogen, sugar, calcium, cholesterol), gastrointestinal roentgenograms with barium, careful stool and urine examinations (including cultures) and intravenous pyelography might be revealing. Endocrine disturbances, especially of the pituitary, thyroid and ovary, may cause retarded growth. Endocrinological study would include basal metabolism, roentgen studies of epiphyseal center development and possibly estimations of 17-ketosteroids in the urine. The appropriate treatment would depend on the particular glandular disturbance, i. e., a hypothyroid child will grow rapidly when thyroid is administered. Testosterone, 10 mg. daily by mouth over a two month trial period, will often stimulate growth when no other cause can be found. Testosterone therapy should be stopped when any evidence of stimulating sex development is noticed.

Anorexia nervosa and other psychogenic disturbances might so interfere with the appetite and intake of food as to stunt growth. Information as to whether this child has been a "behavior problem" and whether she has other emotional dif-

Cervical sympathetic block following apoplexy, in which hemorrhage can be reasonably excluded, is a valuable emergency procedure (J. A. M. A. 136:659-664 [1948]). The article in the *Saturday Evening Post,* however, emphasizes the effect of repeated blocks or sympathectomies in advanced cases and here relies heavily on a California report (*Arch. Surg.* 61:286 [Aug.] 1950). This part of the problem is still in the experimental stage. The mechanism of relief in the advanced cases is unclear, and the value of the procedure is highly debatable.

TREATMENT OF OSTEOPOROSIS

***To the Editor:*—May I have the latest information on the treatment of osteoporosis in a lower leg after healed fracture with impaired circulation to the foot? The patient is a woman of 40 years. Her blood calcium is 9.5 mg. per 100 cc., and she has a basal metabolic rate of —8 per cent. She takes 2 grains (0.12 Gm.) of thyroid a day.**

H. M. F. Behneman, M.D., Palm Springs, Calif.

ANSWER.—Localized osteoporosis usually is due not to any metabolic or endocrine disturbance but rather to a localized disease process, oftentimes with traumatic causation, which results in disturbed circulation to the part and in partial or complete immobilization. Fracture is a common cause, especially if prolonged immobilization in a cast and non-weight-bearing are required. From the meager information supplied, it is assumed that these circumstances reasonably obtained in the case in question and that the fracture was recent. The normal blood calcium substantiates the absence of metabolic fault; the apparent hypothyroid state (controlled by thyroid medication) is not pertinent to the localized osteoporosis. Since the bone decalcification is due to a local lesion, treatment should be essentially local. Measures to normalize circulation should be emphasized. Use of massage, exercises, contrast baths and passive vascular exercises (Buerger's exercises) should be of value. The most important single factor is the establishment of as nearly normal weight bearing on this extremity as is possible, as soon as possible. This will serve more than anything else to normalize function and metabolism in the affected bone.

Usually measures of benefit for generalized decalcification are of little or no help (high protein diet with androgen or estrogen therapy). Recovery of normal or nearly normal bone usually results if the management can be successfully instituted, although recalcification is notoriously slow.

Rh NEGATIVE WIFE, Rh POSITIVE HUSBAND

***To the Editor:*—I would appreciate advice on the following case: The wife's blood is group O, Rh negative, and the husband's, group O, homozygous, Rh positive (type Rh_1Rh_2 [CDe/cDe]). The only child is group O, Rh positive (type Rh_2 [cDE/cde]). The second pregnancy proceeded normally, antibodies developing in low titer at the twenty-sixth week. The titer gradually rose until the thirty-fifth week, when it was 1:512 in serum albumin. No blocking antibodies ever developed. At the thirty-sixth week the titer doubled, but labor was not induced. A few days later the child died in utero. The patient has been told that in all future pregnancies the child may die in utero or, if born alive, will require exsanguination-transfusion. If this is correct, can anything be done to prevent an antibody response? Is hapten of any use? Can it be obtained? Does the administration of vitamin K and progesterone throughout pregnancy prevent the passage of antibodies through the placenta? If treatment will not prevent fetal damage, should the patient be allowed to become pregnant again?**

V. N. Gordon, M.B., Ch.B., South Africa.

ANSWER.—The husband is Rh positive and almost surely homozygous, while the wife is Rh negative and strongly sensitized to the Rh factor. Under such conditions, every child will almost surely be Rh positive and therefore severely erythroblastotic; in fact, it is very likely that every fetus will be stillborn. Only in exceptional cases will a viable erythroblastotic baby be born that can be saved by multiple transfusions of Rh-negative blood or by exchange transfusion (East, E. N., and Mair, C. M.: Intensive Immunization of an Already Sensitized Rh-negative Woman: Birth of a Mildly Diseased Baby, *J. Lab. & Clin. Med.* 34:983 [July] 1949). With regard to the reference cited, it should be pointed out that the title of the article is misleading, because the clinical course indicates that the baby was severely affected and was lucky to have survived. It was only after nine transfusions of a total of 560 cc. of blood over a period of 10 weeks that this baby finally recovered.

The couple may decide that, despite the odds against success, they wish to try again. A stillbirth would be practically inevitable, but by inducing labor four to six weeks before term one might succeed in obtaining a viable baby. It would be far wiser to practice contraception; should the wife become pregnant, a therapeutic abortion would be indicated. Therapeutic abortion is justifiable, because such a pregnancy is almost certain to terminate with a hydropic stillbirth, and such stillbirths are associated with increased danger to the mother from toxemia and postpartum hemorrhage. If the patient becomes pregnant a second time, sterilization of the patient or her husband should be broached. If the couple is very anxious to have another child, they could adopt one, except that, in general, adoption agencies tend to give priority to childless couples. If the temperament of the couple is suitable, artificial insemination from an Rh-negative donor may be resorted to; this has never failed. However, one must bear in mind the moral and legal implications of the procedure (McCurdy, R. N. C.: The Rhesus Danger—Its Medical, Moral, and Legal Aspects, London, Wm. Heinemann Medical Books, Ltd., 1950). At least one court has found Rh sensitization grounds for divorce, maintaining that husband and wife are not sterile and could have children with other spouses of compatible Rh type.

Once a patient has become sensitized to the Rh factor, nothing can be done to eliminate or reduce the Rh antibody titer. The so-called Rh hapten has proved inert both *in vitro* and *in vivo* and is not recommended for treatment (Unger, L. J.: Studies on Preventive and Curative Treatments for Rh Sensitization, *Am. J. Obst. & Gynec.* 58:1186 [Dec.] 1949). Univalent Rh antibodies which are responsible for the disease, readily pass through the placenta, and vitamin K, progesterone and other drugs cannot prevent the placental transfer of antibodies (Wiener, A. S.: Rh Factor in Immunological Reactions, *Ann. Allergy* 6:293 [May-June] 1948).

PROCAINE PENICILLIN AND SULFONAMIDES

***To the Editor:*—There have been reports that the procaine base part of the procaine penicillin preparations has an inhibitive action on sulfonamides, that the procaine part of a·1 cc. dose was enough to make concomitant sulfonamide therapy impossible. Is this correct? Can penicillin be expected to be stable for any length of time in a 3 per cent aqueous solution of sodium bicarbonate?**

R. J. Kent, M.D., Savannah, N. Y.

ANSWER.—Procaine penicillin preparations contain about 120 to 125 mg. of procaine to each 300,000 units of penicillin per milliliter. Woods has demonstrated that a small quantity of paraaminobenzoic acid interferes with the effects of sulfanilamide and sulfapyridine and that procaine had a similar but delayed effect. This delay is probably due to the time involved in the enzymatic hydrolysis of procaine to paraaminobenzoic acid. In vitro studies show that paraaminobenzoic acid must be present only in a ratio of 1:2,000 to inhibit sulfanilamide but a concentration of 1:70 is necessary to inhibit sulfathiazole and the more soluble sulfonamides, such as sulfadiazine and sulfacetamide.

Studies in man indicate that after an injection of 1,500,000 units of aqueous procaine penicillin, appreciable levels of free procaine or paraaminobenzoic acid could not be demonstrated in the blood stream of over half the subjects tested, but evidence of an acetylated derivative of paraaminobenzoic acid was found. In 30 per cent of those tested, concentrations of less than 0.1 mg. of paraaminobenzoic acid per milliliter of serum were found, and 20 per cent showed insignificant traces of procaine.

Both the procaine and the acetylated paraaminobenzoic acid may be disregarded for inhibitory effect since the former is present in too low a concentration and the latter is relatively inactive. However, in the doses administered 30 per cent of the subjects tested did have blood concentrations of paraaminobenzoic acid sufficient to theoretically inhibit the action of sulfanilamide and sulfapyridine, but not sulfathiazole, sulfadiazine and other more soluble sulfonamides.

The procaine from procaine penicillin is released slowly, which probably accounts for the failure to attain a significant blood level of procaine. In addition, the paraaminobenzoic acid formed is excreted with relative rapidity. Therefore, the low total amount of procaine in procaine penicillin preparations, as well as its slow rate of release into the blood stream, and the rapid rate of excretion of paraaminobenzoic acid would make negligible any inhibitory effect of procaine penicillin preparations on the more soluble sulfonamides.

The stability of solutions of unbuffered sodium penicillin G kept at room temperature is rather short; within two days more than half of the original potency is lost. When kept at 10 C. and when a 0.1 M citrate buffering system was used, little appreciable loss was noted after 40 days, with but 20 per cent loss of potency after 80 days. Sodium bicarbonate would have slight preservative action, since the products of penicillin decomposition are acid, but the stability would be only slightly longer than for unbuffered solutions.

CHEMICALS USED IN TANNING LEATHER AND IN SHOE POLISH

To the Editor:—What kind of chemicals are used in tanning leather for tan and black shoes, and what chemicals are used in the material for polishing both types of shoes? Is is possible to absorb any of this material? What effect would one experience?

Lester V. Stallsmith, Ph.D., Wilkes-Barre, Pa.

ANSWER.—Leather intended for black and for tan shoes undergoes the same early treatment. Such leather may represent the full thickness of some skins, such as calf skin, or a split of thicker hides, such as *from* cows. *Preparation prior to tanning* involves many steps and many chemicals. Among other chemicals are lime, sulfites, mineral and organic acids, amines and enzymes. Tanning may be accomplished with a variety of agents, including chrome, aldehydes, quinones and vegetable and synthetic tannins. Tanning is followed by oiling and softening and at times splitting and artificial graining. In due course some leathers are dyed, otherwise colored or enameled. Paraphenylendiamine used to be extensively employed but has largely disappeared. Earlier, too, common solvents included the dangerous benzene methanol and nitrobenzene. Now various other alcohols, esters and naphthas are used. The choice of coloring agents is wide, but aniline dyes in black and brown are mostly used. Despite the protean steps and agents involved, good leather as made into shoes is without significant danger to the prospective wearer. Rarely on a basis of allergy skin affections may arise.

The formula for black shoe polishes is typical: 5 parts montan wax, 15 parts ceresin wax, 5 parts beeswax, 2 parts oil-soluble nigrosin and 50 parts turpentine. For tan polishes the same formula but without the coloring agent may be used, or low quantities of brown dyes may be introduced. Substantially no danger derives from their use. There is enormous variation in polish and dye constituents, and some brands may contain harmful agents.

SLIGHT PTOSIS OF UPPER EYELID

To the Editor:—A 14 year old girl has had slight blepharoptosis of the left eye since the age of 7. Some days it is slight; some days it is more noticeable. The girl is otherwise normal. I wish to know the possibility of a nonsurgical treatment, particularly the action of neostigmine, and the relation of this disorder to generalized myopathies.

Manuel Besoain-Santander, M.D., Santiago, Chile.

ANSWER.—Since there is no other abnormality and ptosis has been present for seven years with some variation in degree, the two most important diagnoses to consider are myasthenia gravis and progressive nuclear ophthalmoplegia. To differentiate between the two, a diagnostic injection of 1.5 mg. of neostigmine combined with 0.6 mg. of atropine should be given. A positive response of disappearance of the ptosis will favor a diagnosis of myasthenia gravis. The ptosis of progressive nuclear ophthalmoplegia will not respond to neostigmine. In this disease, ptosis often is the first symptom; it may be unilateral or bilateral and may be present for a number of years before the extraocular muscles are affected. The disease is progressive and the extraocular muscles eventually will become affected. Also, strong hereditary factors are involved, so that a careful search of the family history should be made. Progressive nuclear ophthalmoplegia may be seen in certain types of progressive muscular atrophy, but rarely with amyotrophic lateral sclerosis. It is observed also with tumors or vascular lesions of the brain stem, in multiple sclerosis, tabes, dementia paralytica, intoxication from lead, botulism, Wernicke's disease, and as a result of injuries. So far as nonsurgical treatment is concerned, the use of the "crutch" glass is probably the best device available. Neostigmine would be of value only if a diagnosis of myasthenia gravis is made.

NEW GROWTHS IN BREASTS OF INFANTS

To the Editor:—A 9 month girl has a firm, movable, discoid, nontender, subcutaneous mass, about 2.5 cm. in diameter, in the left breast. The center of the mass corresponds to the nipple but does not appear to be attached to the skin. *Moderate prominence* of the breast is obvious. The mass has been present since the child was 1 month old and appears to have grown slightly in recent weeks. I have observed this child almost daily, and she appears to be in perfect health. I would appreciate a brief discussion of the differential diagnosis.

M.D., Canal Zone.

ANSWER.—New growths of the infant breast are extremely uncommon. They are uniformly benign. Among those that have been observed are dermoid cyst, hemangioma and a rare intraductal papilloma with bleeding from the nipple. *The single* case of intraductal papilloma presented a soft, centrally located swelling. Pressure about the nipple produced a bloody discharge from the nipple.

These must be clinically differentiated from the common mastitis neonatorum which may appear immediately or shortly after birth and persist for a variable time. Occasionally this may be unilateral and persist for several months. As a rule, a flat, diffuse and slightly nodular swelling is palpable beneath the nipple and areola. No treatment is necessary, since the condition subsides spontaneously.

A cyst is palpable as a well defined and rounded mass located about the margin of the areola. Hemangiomas are more prone to appear in the parenchyma of the breast. They occur as soft, compressible and diffuse swellings. When deeply located and cavernous in type, there is only a faint, if any, bluish discoloration of the overlying skin.

LATENT SYPHILIS OR FALSE POSITIVE REACTION?

To the Editor:—A 42 year old woman had a 2 plus Kahn reaction of the blood in 1942. In September 1949 the state health department reported the following reactions: blood Kline, Wassermann and Kolmer positive and blood Kahn doubtful. A private laboratory reported the Kahn blood reaction positive at the same time, and another private laboratory gave the following results of blood tests: quantitative 10 units and Kahn, *Kline, Mazzini and Pangborn reactions strongly positive. The spinal* fluid in 1949 was clear and colorless, with 1 white blood cell, 1 lymphocyte, negative Pandy reaction, total proteins 100 mg., negative Kahn reaction, gum mastic 000000 and negative Kolmer reaction. Results of Kahn and Kline tests of the blood were positive, quantitative 4 units, Kolmer negative and Kline cardiolipin positive. A blood Kahn reaction of the blood was reported positive in July 1950, with 4 quantitative units. This patient denied having had venereal disease or having been treated for it. Results of her physical examination are normal. She had the usual childhood diseases and scarlet fever, asthma and eczema. In 1938 her tonsils and adenoids were removed; in 1942 she underwent a right nephrectomy and in 1949 an appendectomy. Does this patient have syphilis? Does the protein level indicate neurosyphilis? What treatment would you suggest?

M.D., Ohio.

ANSWER.—This patient has either late latent syphilis or a biologic false positive serologic reaction for syphilis. One cannot say which diagnosis is correct on the basis of standard serologic tests for syphilis. The abnormally high spinal fluid protein suggests central nervous system disease. It is unlikely that this disease is syphilis because of the negative spinal fluid complement fixation. This disease, whatever it may be, might be responsible for the false positive blood reaction. If, on repeated examination, the spinal fluid protein is still abnormally high and no cause can be found, then antisyphilitic treatment may be given. Treatment is given only because a definite diagnosis cannot be made and to give the patient maximum protection for the future in case she does have syphilis. A total of 6,000,000 units of procaine penicillin in oil with 2 per cent aluminum monostearate, given in 10 doses over a period of two to three weeks, should be adequate therapy.

RETARDED GROWTH

To the Editor:—A 7 year old girl, weight 30 pounds (14 Kg.), height 37¼ inches (95 cm.), has a normal history, with the usual childhood diseases. She has a poor appetite, desiring primarily carbohydrates, and takes about two hours to finish her meal. Her intelligence quotient is above average. Physical examination discloses no abnormalities. The parents are 5 feet 7 inches (170 cm.) and three other children are normal in height and weight. This girl has grown 1 inch (2.5 cm.) and has gained about 4 pounds (2 Kg.) in the past year. The parents are apprehensive concerning the weight and growth of this girl.

C. L. Qualls, M.D., Beaver Dam, Wis.

ANSWER.—*Heredity* and environment apparently do not play a role in this instance, as the parents and other siblings are normal. Although the physical examination disclosed no abnormalities, certain congenital defects may be discovered only by intensive studies. Congenital cardiovascular genitourinary and gastrointestinal hidden defects may stunt growth and development. Consequently roentgenograms of the chest, electrocardiograms, blood chemistry determinations (nonprotein nitrogen, sugar, calcium, cholesterol), gastrointestinal roentgenograms with barium, careful stool and urine examinations (including cultures) and intravenous pyelography might be revealing. Endocrine disturbances, especially of the pituitary, thyroid and ovary, may cause retarded growth. Endocrinological study would include basal metabolism, roentgen studies of epiphyseal center development and possibly estimations of 17-ketosteroids in the urine. The appropriate treatment would depend on the particular glandular disturbance, i. e., a hypothyroid child will grow rapidly when thyroid is administered. Testosterone, 10 mg. daily by mouth over a two month trial period, will often stimulate growth when no other cause can be found. Testosterone *therapy should be stopped when any evidence of stimulating* sex development is noticed.

Anorexia nervosa and other psychogenic disturbances might so interfere with the appetite and intake of food as to stunt growth. Information as to whether this child has been a "behavior problem" and whether she has other emotional difficulties and maladjustments, besides the slow eating habits and poor appetite, would aid in diagnosis. In certain circumstances psychiatric therapy might help. Fatigue may cause this lack of appetite. Shortening school hours, more sleep, moderation in athletics and periods of relaxation before meals might help. Any anemia should be corrected. Recently vitamin B_{12} therapy (10 micrograms or more daily) has caused certain undernourished children to gain and grow rapidly when no other cause could be found. Also occasionally 5 units of insulin given a half-hour before meals will greatly stimulate the appetite.

HEREDITARY ASPECTS OF CELIAC DISEASE

To the Editor:—A four year old girl has been given a diagnosis of celiac disease. She has been to one of the larger medical centers, is being treated and is progressing nicely at this time. The parents (26 and 30 years of age) have been told that they should not have any more children because of the possibility of celiac disease in other offspring. What is the probability?

_M.D._, Texas.

Answer.—Several more or less clearly defined entities have been described in the group composing the celiac syndrome; these are classified by Brennermann as follows: (1) classic celiac disease or idiopathic steatorrhea, (2) starch intolerance, (3) congenital pancreatic insufficiency, (4) chronic mechanical obstruction of the pathways of digestion and absorption, (5) cases presenting or suggesting the celiac syndrome but which do not fall into the above group. Although any one of these may occur in more than one member of a family, only cystic fibrosis of the pancreas (congenital pancreatic deficiency) is a congenital and familial disease, occurring in approximately one fourth of the siblings in affected families. The disease in the described case probably falls in the group of classic celiac diseases. There would not be any contraindication for the parents to have more children unless a diagnosis of cystic fibrosis of the pancreas had been made. Perhaps it would be well to consult further the clinic making the diagnosis.

IDIOPATHIC SCOLIOSIS IN A YOUNG GIRL

To the Editor:—What is the treatment for so-called idiopathic scoliosis of moderate degree involving the dorsal region in a young healthy girl of 11? Is physical therapy ever successful in such cases? Is surgical fusion the only accepted method?

_M.D._, Florida.

Answer.—The accepted treatment for idiopathic scoliosis in a girl of 11 years depends on several factors. Foremost of these are (1) severity, (2) rapidity and degree of progression, (3) location and extent of the curves and (4) degree of compensation. In most cases careful observation over a period of months, and in some cases a few years, is necessary to decide whether or not fusion is indicated. The role of physical therapy in the treatment of scoliosis is questionable, but, if exercises as prescribed by a competent orthepedist or physiatrist are carried out during the period of observation, no harm would be expected from this treatment. If it is decided that sooner or later fusion is necessary, the question of correction and compensation is complicated as is the decision as to the extent to which the spine should be fused. Most orthopedic surgeons have had special training in the management of scoliosis, and it is suggested that the child in question be placed under the care and observation of one having had such training.

HOMOSEXUALITY IS NOT HEREDITARY

To the Editor:—A 19 year old boy, whom I have known since he was 3, recently told me that he is homosexual and wants help desperately. His father is a personal friend of mine. I can say the same of the young man's grandparents and all his near relatives. No sign of this abnormality is in the family to my knowledge. I would like your advice.

_M.D._, Massachusetts.

Answer.—The inquirer intimates that homosexuality is hereditary. This is not correct. It is a developmental arrest in the evolution of a personality. In varying degrees the subject remains psychologically immature in his attachment to and relation with other persons. There are many degrees of homosexuality. It is a normal phase in personality development in early adolescence. It remains a basic feature of every person's life, but he passes through the phase when he is more interested in members of his own rather than of the opposite sex. It becomes pathological in the adult who maintains such a relation for his sexual outlets. Help is available and can be effective for the homosexual person who desires it. The treatment, however, is entirely psychiatric and is nearly always a prolonged undertaking, lasting, even with intensive treatment, many months or even years. For those persons who do not want to change their makeup and even those who are not highly motivated in seeking help, treatment is practically useless.

PERSONALITY CLASSIFICATION

To the Editor:—About 1920 two men in Vienna categorized people into, I believe, sympatheticotonics and parasympatheticotonics. Jung divided people into extroverts and introverts. Now there seems to be a tendency to divide them into "adrenocorticotropics" and "anterior pituitaries." Is there a relation between these three divisions? Are the sympatheticotonics usually extroverted and usually adrenocorticotropics and vice versa?

Paul C. Craig, _M.D._, Reading, Pa

Answer.—Many attempts have been made to classify people according to some assumed functional or anatomic differences None of these, however, has a scientifically sound basis. Although a few persons show certain characteristics suggestive of an overactive sympathetic or parasympathetic nervous system, such a classification is not universally applicable. This is also true regarding introverts and extroverts, since many persons would belong to neither of these groups. There is certainly no evidence that there is a relation between the degree of introversion or extroversion, sympathetic or parasympathetic activity and adrenocorticotropic or anterior pituitary activity.

SCHIZOPHRENIA

To the Editor:—My 36 year old nephew has had schizophrenia since he was 18 years of age. Radical lobotomy, in January 1950, improved his condition substantially. He still shows signs of psychosis, like confabulation, obscene language and tremendous stubbornness. Is there some form of treatment (hormones) that might bring further improvement?

_M.D._, Connecticut

Answer.—From the history as given, it seems unlikely that any appreciable improvement could be effected by hormone or other therapy in this case. In any case of schizophrenia of 18 years' duration, treatment by any of the methods now employed will do little. In the case of some males, diethylstilbestrol has been used in order to make the patient more docile and manageable. However, no great dependence can be placed on this treatment, though theoretically it may have some validity if disturbed conduct seems to be associated with uncontrolled sexual impulses.

NEPHROTIC SYNDROME

To the Editor:—For the past several years I have suffered from the so-called "nephrotic syndrome," with massive edema, urine containing albumin (4 plus), reversed albumin-globulin ratio, hypoproteinemia, blood findings (except for albumin and globulin) within normal limits. Can you inform me as to any of the latest treatments for this condition? I have tried the sodium lactate-potassium acetate treatment and the ion exchange treatment. Is there anything else that may help me? What about ACTH or cortisone?

_M.D._, New York.

Answer.—Pituitary adrenocorticotropic hormone (ACTH) and cortisone have been reported to produce diuresis, loss of edema and general improvement in children with the nephrotic syndrome. This treatment is still highly experimental and should be carried out under expert supervision. Expensive as they are, these hormones are more economical to use than human salt-free serum albumin.

DILATATION OF PUPIL

To the Editor:—Which drug, and in what concentration, is most advisable for enlarging the pupil sufficiently to permit routine eye ground examination by a general practitioner and allow the pupil to return to its normal size and mechanism in the shortest period of time?

R. J. Kent, _M.D._, Savannah, N. Y.

Answer.—Four per cent cocaine hydrochloride, instilled three times at five minute intervals, is probably the simplest procedure for securing maximal dilatation for fundus examination and prompt subsequent narrowing of the pupil and restoration of accommodation. Dilation of the pupil does, of course, precipitate an increase of tension in an eye predisposed to glaucoma, and the tension should be determined with a tonometer beforehand.

ERUPTION OF DECIDUOUS TEETH

To the Editor:—Is there evidence that the deciduous teeth erupt because of pressure of hyperemic tissue beneath their roots? Could this hyperemia account for the rhinorrhea that often accompanies teething? If not, what other mechanism can account for the eruption of teeth?

_M.D._, Louisiana.

Answer.—The exact mechanism of eruption of deciduous teeth is still a controversial problem. Periapical hyperemia probably plays a role in eruption. However, this hyperemia probably is not related to the rhinorrhea and other symptoms that sometimes occur at the same time as teething. A comprehensive review of the theories of eruption was published in the *American Journal of Orthodontia and Oral Surgery* (27:552 [Oct.] 1941).

DOES THE HEALTH OFFICER HAVE STATUS?

Chairman's Address

CARL N. NEUPERT, M.D

Madison, Wis

Health is the leading interest of the reading public for those over 40 years of age. Newspaper and magazine editors recognize this interest and capitalize on it. It is one of the most important issues before Congress. Wherever a group of people gather there is seldom agreement as to the best method for improving health. There are those who advocate placing the responsibility for providing good health for all in the hands of the federal government. Others have recognized serious dangers in such an approach—danger not only to America's democratic form of government but in the strong possibility that such a system would not result in health improvement, the very thing it is intended to accomplish.

The only sound plan for reducing the load of sickness is one which prevents illness. Compulsory health insurance cannot be expected to accomplish this. The magnitude of the administrative machinery incident to such a plan would stifle the development of plans aimed at the prevention of illness. The platform of the American Medical Association highlights the extension of voluntary health insurance and the promotion of nationwide public health administration on the local level. Voluntary health insurance is moving ahead rapidly with physician support, but are doctors really pushing the organization of full time local health departments? Lack of support by physicians on an individual basis is one of the obstacles to progress in public health.

One of the more serious of these obstacles is the shortage of trained medical public health administrators, traditionally referred to as health officers. Limited opportunity for financial gain as compared with that from the private practice of medicine is one reason for this shortage, but more important is the scant recognition by many physicians of the status of the health officer. He has standing with the general public. People are aware of the substanial contribution of public health departments in the reduction of communicable diseases and environmental sanitation hazards and in the advancement of maternal and child health.

The American Medical Association has recognized the special status of the trained health officer, and the specialty Board of Preventive Medicine and Public Health has been established, but the rank and file of practicing physicians have not bothered to look into the matter thoroughly and apparently still regard this developing field of medicine rather lightly. This appears to be true of many in high places in medicine, most of whom were graduated from medical school some years ago when preventive medicine and public health occupied a minor position in their training.

Most physicians will agree that public health has proved its value in the prevention of diseases, the prolongation of life and the promotion of physical and mental efficiency. If this is recognized, one must recognize the part that the health officer has played. In my state it was a practicing physician and his county medical society, with the backing of the state medical society, who convinced the state legislature of the need for a state board of health nearly 75 years ago. The recognition of need for this unit originated not with the general public but with physicians. These physicians saw clearly the need for a central body by which the perplexing problems dealing with widespread epidemics and with sanitation could be studied and solved. The rural areas, then comprising nearly all of the state, were in desperate need of help. Eventually they got it as a result of action based on reports of illnesses and deaths that were gathered and analyzed by the state board of health.

It is a matter of record that the board of health has taken every advantage of its position as an official body charged with "responsibility for the health and life of citizens" to push immunization so that smallpox, diphtheria and whooping cough, formerly killers of hundreds of children in the state, are practically nonexistent today. This has been accomplished by direct appeal to parents with the cooperation of practicing physicians. The provision of safe public water supplies and sewage disposal has now advanced so that typhoid has practically been eliminated.

The older practicing physicians have witnessed this tremendous change—and it has been tremendous. Today medical students in my section of the country have little or no opportunity even to see a case of smallpox or diphtheria or typhoid before graduation and have little prospect of seeing them in their practice. These are accomplishments largely creditable to the efforts of public health departments. They are familiar to the public. Similar developments differing somewhat from state to state have taken place throughout the country.

Tuberculosis has responded to the combined efforts of physicians, voluntary agencies and health departments. No attempt is here made to evaluate the effect of the various factors such as advances in surgical treatment, the antibiotics, efforts of voluntary agencies and isolation in sanatoriums in bringing about this result. Some states have relatively high rates of tuberculosis morbidity and mortality, coupled with limited facilities and resources with which to combat them, while others are more favorably situated. These latter have low rates, adequate sanatorium facilities available

---

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Ninth Annual Session of the American Medical Association, San Francisco, June 30, 1950.

to all citizens at public expense and relatively few exposures to infectious cases. As a result, there is a prospect that tuberculosis will be in a position of minor importance as a cause of morbidity and mortality in these states in the near future. It is significant that in these states there have been aggressive, effective tuberculosis control programs carried on by public health departments.

The remarkable reduction in maternal mortality is another example of the result of good teamwork between the official health agencies and the practicing physicians. In my state, Wisconsin, 99.9 per cent of all deliveries are performed by physicians and the maternal mortality rate has been reduced from 3.9 per 1,000 live births in 1936 to 0.6 in 1949. Similar accomplishments can be cited for metropolitan areas such as New York City and for states where health department functions are on a county basis.

In Wisconsin a significant factor in that reduction has been the activity of the state health department. No attempt is here being made to evaluate the weight of various factors responsible for the low maternal death rate. It is in order, however, to call attention to certain of these factors as a part of the evaluation of the importance of health department activities in improving maternal health. The state health department has repeatedly called the attention of physicians to the preventable hazards of pregnancy and encouraged pregnant mothers to avail themselves of the guidance and care of their physicians early in pregnancy. Without this emphasis the results might have been much less favorable. From analysis of data taken from birth certificates and death certificates, specific risks were highlighted, such as those associated with exceptionally high incidence of cesarian section occurring in some localities, the need in smaller hospitals for having plasma or blood at hand to combat shock resulting from hemorrhages associated with delivery and the adverse effect of precipitate labor due to drugs or manual interference. The health department produced data on the risks; the practicing physicians saw to it that the information was the basis for action.

Work on other public health problems is just beginning. The problems of excessive numbers of premature births and large numbers of neonatal deaths and the problems associated with an aging population, such as the chronic diseases, are prominent. Even though proved technics for attacking problems like heart disease, cancer and diabetes are now available only to a limited extent, they are in the process of development and give promise of good results. Screening technics that have been in operation in some areas have uncovered appreciable numbers of unsuspected cases of chronic disease in the early stages while prospects for recovery are greatest. Inauguration and successful operation of these technics require the cooperation and "carry through" of a full time local health department to supplement the key figure, the practicing physician.

Those who are best qualified to give an opinion are agreed that coverage of the country with full time local health departments is a necessity if physicians are to make real progress in the problem of reducing the number of sick persons in need of medical care. Among other things, they are aware of the shift to greater utilization of hospitals for diagnosis and care of patients and the accompanying reduction in contact of the physician with the family in the home. The public health nurse has become a valuable asset to the physician and as a result to the family. She can supply him with valuable information on family living conditions that is important to his management of the illness.

The American Medical Association is committed to expansion of local health councils as an integral part of its program to find an answer to the need for improving the health of those living in rural areas. The Association was the first national health agency to endorse complete coverage of the nation with full time local health departments. Practicing physicians have a stake in the success of that development. To bring it about, there must be trained medical health officers to head these local health departments. There is at present no reservoir of trained public health physicians to do that bigger job. There is a serious shortage of health officers to fill existing vacancies.

Among the factors which appear to contribute importantly to that shortage is the lack of enthusiasm and of appreciation by practicing physicians for the possibilities for constructive service in the work of health officers. This is held to be due largely to lack of information. There may still be a carryover of the contempt for the political appointee, often a semiretired physician, who had no special training for the complex duties he assumed. According to Smillie[1] that period ended about 1925. Whatever the reasons for its existence, there is need for a solution to the problem of shortage of health officers. The status of the health officer is of concern to all physicians.

JUVENILE DELINQUENCY

Chairman's Address

M. M. NICHOLSON, M.D.
Washington, D. C.

Mr. J. Edgar Hoover, Director of the Federal Bureau of Investigation, said on May 19, 1950:

> The United States is sadly neglecting its most precious assets, the citizens of tomorrow. There is a rapidly rising rate of crime in youth. Fifty per cent of the crimes against property are committed by people under 20 years of age. . . . Perhaps the disappearance of the woodshed of my generation has had its effect. . . . There is no satisfactory substitute for discipline in developing character. . . . Any city in the country would strike a telling blow against crime within 24 hours if the people had the will and determination to eradicate the breeding places of crime.

The juvenile delinquent is not a type of child. He has gone astray as the result of insufficient guidance and care. The juvenile delinquent is not depraved; he is just deprived.

MENTAL AND PHYSICAL HEALTH

There is disagreement among the many surveys of physical health, but the majority of careful studies accept the fact that the health history does not influence delinquency. Delinquents may have carious teeth, because they were too difficult for the dentist to manage, or rickets, because the parents did not recognize the need for vitamins. The Gluecks found that only one sixth of the boys taken to the Judge Baker Foundation were in poor physical condition.

Of 4,000 repeated offenders appearing in the juvenile courts of Chicago and Boston, over 70 per cent were mentally normal. Emotional maturation may be low,

but we must take into consideration that a test done soon after placement in an institution is influenced by the special situation in which the child is at the time.

COST OF CRIME

Americans have the reputation of never wasting money. Shall we consider the cost of crime? The Wickersham Committee (1931) estimated it as 15 billion dollars a year. This was five times the total expenditure for education that year. But this money value pales when we consider that the most pernicious waste is not material but moral. Crime leaves a trail of death and disability through disease and violence. What kind of integrated social organism can the America of the future hope for, if so many of its future citizens display so early in life a tendency toward, or actually exhibit, disregard for law and order?

ECONOMIC GROUP AND NATIONALITY

The idea that juvenile delinquency is more prevalent among poor children has been corrected. Some statistics taken from institutionalized children gave a false impression, since the children of wealth are not placed in institutions. In the first place, wealth and social position provide a certain degree of immunity against arrest. In the second place, when financial restitution is made, the damage is usually not even reported to the police. Some statistics were taken by area. This means that one square mile in a poor neighborhood with a dense population is numerically compared with a wealthy neighborhood where space is occupied by gardens, lawns and few children.

Rockless and Smith found that foreign-born white children show a smaller rate of delinquency per population unit than native-born white children.

HOME CONDITIONS

The home has the child completely from birth until 5 years of age. After the child starts school, he is at home 16 of the 24 hours of a day. Thus the home may outweigh the influence of the school. Shelden and Eleanor Glueck found that nine tenths of the delinquents studied came from broken or poorly supervised homes. The broken home is one of the weightiest factors in juvenile delinquency, because it leaves the child with no attachment on which to grow; he is helplessly adrift on the rough sea of life.

Even if the home is broken, the child with brothers and sisters will tell you he cannot disgrace his family. The larger the family the more stable the home life. A Metropolitan Life Insurance bulletin for February 1950 showed that there were 44 divorces per 1,000 couples without children, 15.3 divorces when the couple had one child and 4.6 when they had four or more children. It is estimated this 4.6 per cent would be under 1 per cent if children from prevous marriages had not been counted, thereby including the few persons who had four or more marriages with one child each.

CORRECTION OF JUVENILE DELINQUENCY

Family Life.—Parents must be assured that rearing a family is the highest vocation. Children should not be deprived of that solid background which is given by a home and the protective support which is given by parental guidance. The child wants absolute protection with no frustration; hence he must have confidence that his parents will guide him the right way. The view from the top of Niagara Falls is enjoyable only if one has the protection of a strong and reliable rail on which to lean. A child needs protection and guidance until he has acquired and is prepared to use his own judgment. The child who says to a parent, "Well, everyone else is doing it," and thereby succeeds in changing the parent's order, will lose confidence in the parent's decision, because the fact that someone else does wrong is the cause of sorrow and can by no means justify what a young person unquestionably knows is wrong. The "zoot suits" and gangs are just the outward signs of insecurity. They are just "whistling in the dark." The child who has the love and protection of home laughs at these other children. They have to have a gang because they do not have a normal home. I have talked to a gang leader who would gladly have turned over all his leadership to a father in whom he could place responsibility.

Divorce.—The doctor who will take the time to study divorce and to explain its problems to his patients can probably reduce divorce among them 75 per cent. However, if the pediatrician realizes that he cannot help the couple, he can suggest that they go to the "Divorcées Anonymous," an organization recently founded in Chicago in which the couple contemplating divorce are talked to and reasoned with by a person who has gone through a similar trial which ended with a divorce and who later regretted such action. An example of this procedure is found in the case of Mrs. M. Mrs. M's husband spent much of his salary in gambling. She therefore planned to divorce him. Someone told her about "Divorcées Anonymous," and she went to the local office of the association. Here she found Mrs. X (who had divorced her husband for gambling, drinking and infidelity). Nevertheless, she told Mrs. M that she would rather have him even under these conditions and strive to help him rather than ruin the children's lives in a broken home. This made Mrs. M realize that her husband was not so reprehensible after all, so she went home determined to stay with him and help him all she could, thus saving her home from dissolution. Perhaps this will be the outcome in some cases confronting us.

Religion.—The delinquency committee of the White House Conference reported that 37 per cent of 2,191 delinquents studied had absolutely no church connections. Most of the others had little religious training.

A foreign diplomat made the following statement to me: "There is no possibility of trouble in my country because only 1 in 7,000 is a communist." Within 48 hours, his country had joined the satellite nations. Why do we, a nation built on a firm religious foundation, allow the small number of atheists to prevent religious training of our children? George Washington said, "Reason and experience both forbid us to expect that morality can prevail in exclusion of religious principles."

When Columbus landed, his first act was to pray. When those seeking refuge landed in Massachusetts and in Maryland, their first act was prayer. The entire South and Southwest was settled by religious groups who prayed. George Washington frequently prayed, and Lafayette and Washington went together to church in Philadelphia to ask God's guidance during the Revolution. "In God We Trust" was placed on our money. Our testimony in court begins with "I do solemnly swear." The Congress of the United States opens with prayer. Why deprive our children of the joy of prayer or the pleasure of asking the old fashioned "blessing" before meals? The child who has God to rely on is never lonely, lost or in trouble.

Dr. Joseph Hasslein said, "Religion in the home, religion in the school, religion in the heart of every true patriotic man and woman throughout the land—there is the ultimate solution of our problem, and the only genuine remedy for juvenile delinquency and adult crime. All other means are mere palliatives, when this is omitted, or when even—God forbid—it is knowingly slighted. Defying the Divine Will, how can anyone be expected to obey mere creature laws, except under instant pressure?" If the pediatricians of America would determine to stop juvenile delinquency, they would succeed.

ABSORPTION AND CLINICAL USE OF PENICILLIN PREPARATIONS GIVEN IN LARGE ORAL DOSES

A Cooperative Study Utilizing Discontinuous Therapy

PAUL BUNN, M D.

E. R. CALDWELL, M D.
Washington, D. C.
CHARLES ADAIR, M D
Syracuse, N. Y.
MARK LEPPER, M.D.
and
HARRY DOWLING, M D
Chicago

For several years, it has been recognized that penicillin administered orally can be used effectively in the treatment of many infections commonly treated by parenteral administration.[1] Several factors have delayed more widespread use of penicillin by mouth. Since only from 20 to 33 per cent of an orally administered dose of penicillin is absorbed from the intestinal tract,[2] this route was originally considered wasteful of an expensive material. Moreover, since the absorption of the drug is limited to a small segment of the gastrointestinal tract, the period for absorption is short. This, coupled with rapid excretion, causes quite irregular or transitory demonstrable serum concentrations, lasting only from two to four hours, if small doses are employed.[2] The presence of food in the gastrointestinal tract also interferes markedly with the efficient absorption of orally administered penicillin with the result that the drug has had to take precedence over meals in a daily schedule, an arrangement that is usually quite inconvenient. This combination of factors has made the oral use of penicillin less popular than would appear to be warranted in view of its established effectiveness in a number of infections. Because of the recent success of discontinuous therapeutic regimens[3] and because penicillin for oral administration is now less expensive than heretofore, therapy schedules in which large doses of penicillin are given two or three times a day have been investigated.

In this paper there is presented evidence that 500,000 units of various penicillin preparations administered by mouth give a moderately high peak concentration in the blood followed by a lower but consistent level for the next five to eight hours. This large single dose is administered two to three times a day, at eight to 12 hour intervals, without great increase in cost to the patient. Furthermore, the regimen eliminates the difficulty of arranging meals around penicillin schedules as well as assuring the patient a good night's rest. Finally, evidence is presented that this therapeutic schedule is clinically satisfactory.

PLAN OF STUDY

Several penicillin preparations for oral administration have been used in this study (table 1). The majority of patients and subjects received 500,000 unit tablets of crystalline potassium penicillin G. Before a clinical therapeutic trial was made, 40 normal or convalescing subjects were given a 500,000 unit dose orally after an overnight fast, and determination of serum concentration was made at a half, one, two, three, five and eight hours by the method of Randall and his associates (Washington)[4] and by the Tompsett modification of Rammelkamp's serial dilution technic (Syracuse)[5] (table 2). Twenty-six other subjects received 200,000 or 300,000 units, and blood levels were similarly studied and therapeutically effective levels were demonstrated. After uniform absorption and therapeutically effective levels were demonstrated, 104 patients were treated.

Therapeutic dosage in somewhat over half the cases was 500,000 units at 6 : 00 a. m., 3 : 00 p. m. and 10 : 00 p. m. The remainder of the patients received the same amount twice a day, at 10 :00 a. m. and 10 .00 p. m. Both schedules allowed the drug to be given at a time when the stomach was empty, yet with a minimum of inconvenience to the patient and/or the nursing staff. The schedules were changed somewhat for small children to fit feeding and sleeping habits. The dosage was essentially the same in all cases, regardless of severity of infection

SERUM CONCENTRATIONS OF PENICILLIN

The serum concentrations of penicillin in 40 patients given 500,000 units of penicillin orally after an overnight fast were studied (table 2). Serum concentrations in only three subjects were determined at 40, 60 and 120 minutes. At 40 minutes, the average level was 0.8 unit per cubic centimeter. Peak concentration in all was observed at 60 minutes, with an average level of 1.7 units per cubic centimeter. At the end of two hours, all three subjects had a fall from the peak level, the average being 0.43 unit. Serum concentrations were then determined on 40 patients at three hours. The average concentration was found to be 0.19 unit per cubic centimeter, with 95 per cent of the subjects showing demonstrable levels, that is, at least 0.03 unit or higher. At the end of five hours, of the 31 serums tested, 79 per cent showed levels of 0.03 unit or higher, the average being 0.09 unit per cubic centimeter. At the end of eight hours, of 35 serums studied, 49 per cent showed concentrations of 0.03 unit or higher, the average being 0.034 unit per cubic centimeter. Serum levels in 26 subjects following 200,000 to 300,000 units of penicillin administered orally in the fasting state were studied. Again peak concentrations were observed at 60 minutes in the vast majority of the patients. None had a demonstrable level at eight hours. Seventy-five per cent of the sub-

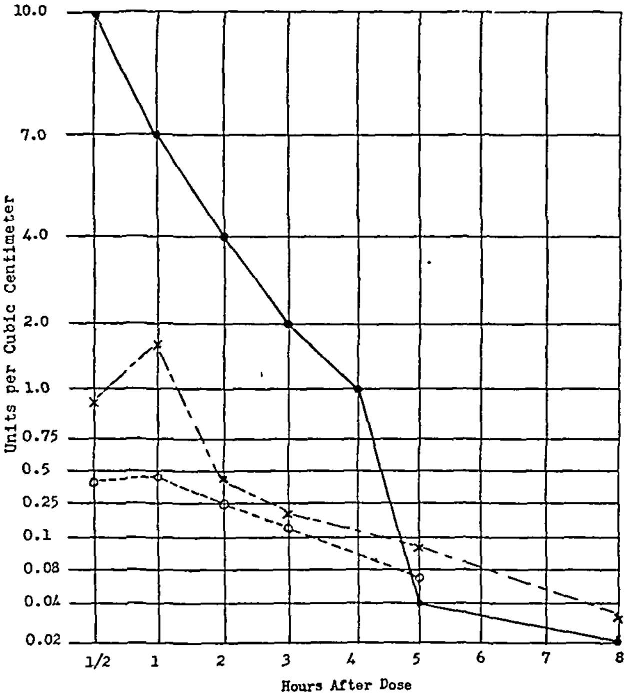
RESULTS OF TREATMENT

Oral administration of penicillin was used in the treatment of 104 patients, with results shown in table 3. Types of vehicles in which the penicillin was administered are shown in table 1.

Thirty patients with lobar pneumonia were treated, with good response in 26 (table 3). Fourteen of the 30 had typed pneumococci in the sputum; six had pneumococci, untyped or classified, and from ten, who had typical clinical lobar pneumonia, pneumococci could not be or were not isolated. Of the 30 patients treated, the temperature returned to 99 F. or below by the end of 30 hours in 24 and to normal before the third day in the other six. Serial roentgen examinations of the chest were made on all, and clearing of process within three weeks was noted in 26. Slow resolution occurred in two, and eventual clearing in these was not completed until 40 days. The course of treatment was from three to 18 days and averaged 6½ days.

One patient, moribund at the time therapy was started, died shortly after the first dose of penicillin. Another patient, a man aged 59, had a pneumococcic infection which failed to respond as expected. A change to the intramuscular route of penicillin administration also failed to alter the clinical disease, and eventual, albeit gradual, improvement followed sulfadiazine therapy.

Seven patients with bronchopneumonia are included in the series. All seven had pulmonary infiltrations by roentgenogram, although solid consolidations were not seen. Bacteriologic findings were not specific. All the patients were acutely ill. Because no therapy other than orally administered penicillin was prescribed, the group is worthy of inclusion in the series. Five of the seven responded in impressive fashion with febrile crisis to normal within 24 hours and complete roentgenographic clearing within three weeks. One patient, a child 1½ years of age, failed to respond until penicillin was administered parenterally after 48 hours, and this case must be considered to represent a failure of oral therapy. The response with intramuscularly administered penicillin was impressive. The remaining patient, aged 91, had a reasonably good over-all response, although no crisis was observed and resolution was delayed.



Comparison of blood concentrations following single doses of orally and intramuscularly administered penicillin. The dash line with crosses indicates 500,000 units orally (average of 40 patients). The dash line with circles indicates 300,000 units orally (average of 25 patients). The straight line indicates 300,000 units intramuscularly (average of 3 patients). All orally administered penicillin was given in a fasting state.

Four patients of the 37 had febrile relapses (temperatures 101 to 102 F.) on the third to the seventh day. Each episode persisted for from 24 to 48 hours and disappeared spontaneously. No extension of the pneumonic process was noted, and therapy was not changed in any.

Eighteen patients with scarlet fever were treated (table 3). They ranged in age from 6 months to 19 years with average age of about 4½ years. Sixteen of the 18 made a good response without complications. In one child, 19 months of age, after an initially satisfactory response, bronchopneumonia of unknown origin developed while he was receiving penicillin orally, and a change to intramuscular administration of crystalline penicillin was considered necessary. Thereafter he made an uneventful recovery. The eighteenth patient had a proper clinical response, but the expected prompt disappearance of rash did not take place. One child, 2½ years old, not included in the series, was unable to retain the tablets by mouth. He received only one day of therapy, was changed to intramuscular injection of penicillin, and made an uneventful recovery. Complications, such as otitis media, rheumatic fever or nephritis, did not develop, at least during the observation period. Therapy extended from five to 18 days. In 14 patients therapy was less than seven days. Approximately 7,000,000 units of penicillin was required on this treatment schedule.

Septic sore throat in 13 patients, with and without acute tonsillitis, was treated (table 3). In all patients, group A beta hemolytic streptococci were isolated from the throats; in none was there abscess formation. Ages ranged from 1 to 52 years, the vast majority of patients being over 20 years of age. For 10 patients, the duration of therapy extended from two to seven days. Most patients received the drug for only four or five days. The results of therapy were excellent in 12 of the 13 patients. Tonsillitis subsided within 48 hours; defervescence occurred within 24 hours, and clinical improvement was satisfactory within four days in this group. In only one patient was there noted slow improvement in the acute tonsillitis. Complete recovery was delayed until the tenth day.

Eight other patients with beta hemolytic streptococcus infections were treated and response in seven was impressive. There were three patients with erysipelas, two each with impetigo and cellulitis (on the nose and leg, respectively) and one with acute tracheobronchitis without pneumonia. Both Streptococcus and Staphylococcus aureus were recovered from the two patients with impetigo. Erysipelas failed to improve until after the sixth day in one woman, aged 74, although her lesion healed without complication thereafter. Evaluation of both cases of cellulitis was difficult because of underlying pathological lesion (varicose veins and skin carcinoma), but in each the infected skin improved in satisfactory manner, though only temporarily.

Thirty-nine patients with beta hemolytic streptococcus infections were treated. In none were there purulent complications. In 90 per cent of the patients the therapeutic response was excellent, although in only one case was oral therapy apparently inadequate.

In table 3 are summarized data on 28 patients with staphylococcic and miscellaneous infections treated with penicillin administered orally two or three times daily. Eminently satisfactory responses were noted in 27 patients. In only one patient with acute pharyngitis, from whom no organisms had been isolated, was there a poor immediate response. Pyuria and/or bacilluria disappeared within five days or less in all patients with urinary tract infections. Both abscesses healed with surgical incision. Cellulitis with pus formation in both patients cleared promptly. Evaluation is difficult in one of these two patients because of an underlying carcinoma, but subsequent surgical excision of this was possible, with clearing of the surrounding inflammation. Although the causative agent in eight cases of acute pharyngitis was not bacteriologically proved, there was response within four days and no complications were observed. Good responses of five cases of Vincent's infection of mouth and gums, two cases each of acute otitis media and sinusitis, five abscesses and cellulitis of the leg in two patients were noted. Surgical drainage was performed as necessary in the majority of abscesses.

Toxic reactions were noted in two patients. In one a moderately severe inguinal and perineal dermatophytid developed after a single dose, and the other had nausea and vomiting. The case of neither patient is included in the therapeutic series because less than one day's therapy was administered. Another patient, whose case is included in the series, had moderately loose stools while on penicillin therapy.

COMMENT

Pharmacologic data and results of clinical studies presented here have been obtained at two institutions. Because clinical material from one or the other was considered inadequate if presented alone, observations from each have been combined. Certain variations in technics have been employed in measuring serum concentrations of penicillin, and patients received different nursing attention. The observations, both pharmacologic and clinical, are sufficiently alike, however, to warrant this combination of results. It must be emphasized that all data were compared only after completion of the entire study. This independent performance of both the pharmacologic and the clinical investigations makes the material all the more valid and valuable.

There are two major differences between the two studies. In Syracuse, seven varieties of carrying agents for penicillin were used in both the clinical and the laboratory studies. As no single one of these was superior to the other, either in therapeutic response of the patient or in blood levels of penicillin, it seems proper to include the results in a single group. The other difference is that a twice daily regimen of 500,000 units penicillin was virtually always employed in Syracuse, whereas in Washington the material was given three times a day. In general, then, the latter patients (56 of the 104) received more penicillin.

The question naturally arises concerning the value of a third dose of penicillin each day for therapy of many infections. In this series, both regimens have proved satisfactory and whether or not the third dose is necessary is less important, perhaps, than the extra security which it allows.

As has been pointed out many times in the past, the vehicle in which penicillin is carried is unimportant, and no single material has proved more efficacious than penicillin given in tap water. It is important, however, to so time the administration of the tablet or fluid that the stomach is relatively empty. Assurance of best absorption is thus best gained. There is no delayed absorption of procaine penicillin in tablet form, the pharmacologic properties of this salt being identical with that of penicillin G.

The preparation labeled penicillin "O" (table 1) deserves comment. The material is an allyl salt of penicillin and presumably has the unique property of having no cross immunity reactions with crystalline penicillin G or any of its salts. Although it cannot be stated from the studies described in this report that it does have this advantage, in at least four other instances it has proved to be useful for persons suffering from delayed type of hypersensitivity reactions due to the administration of penicillin G. In all of these, penicillin "O" was successfully and safely substituted in the presence of either angioneurotic edema or generalized pruritic macular rash. The purpose of its use in this study was to determine its pharmacologic and therapeutic efficacy. In general, periodic blood concentrations follow the curve expected from other penicillin preparations but are somewhat lower. This difference, although minor, was consistent in all subjects. In the dosage employed for patients with infections, the results in all eight patients were identical with those observed when other preparations were used. It is appreciated that most infections are usually overtreated with penicillin.

All patients in this series had normally functioning gastrointestinal tracts at the time oral therapy was instituted. It must be emphasized that in the case of any patient in whom there is gastric dilatation or intestinal hypermotility, it is not advisable to administer penicillin by mouth. Absorption may be so impaired in either circumstance that proper therapeutic response may not be obtained. In general, it is true that the attainment of adequate blood concentrations of penicillin and the maintenance of therapeutic levels is dependent almost solely on the integrity of the gastrointestinal tract.

SUMMARY

Forty normal or convalescent hospital subjects were given 200,000 to 500,000 units of penicillin in a variety of vehicles after an overnight fast, and serum concentrations of penicillin were determined periodically over an interval of eight hours. In approximately 50 per cent of the patients receiving 500,000 units, concentrations above 0.03 unit of penicillin per cubic centimeter of serum were noted at the end of eight hours.

A total of 104 patients with infections were treated. Satisfactory therapeutic response after 500,000 units of penicillin given twice or three times daily was observed in 94 of the patients (90 per cent), and in 6 others (6 per cent) somewhat slower than expected resolution of the infectious lesions occurred. Complete cure eventually took place in the latter patients without change in therapy.

Regimens in which at least 500,000 units of penicillin is administered twice or three times a day are feasible in most cases in which penicillin is indicated, except bacterial endocarditis, meningitis and staphylococcic sepsis. In the staphylococcic sepsis and in certain other infections in which high serum levels of penicillin are required or in which penicillin cannot easily penetrate into the involved area of inflammation, oral therapy is not advocated.

Oral therapy in the majority of cases of infections caused by micro-organisms susceptible to penicillin is safe, easy and reasonably inexpensive. When the drug is administered only twice or three times a day, scheduling of doses to avoid meals is no longer a problem.

three weeks was noted in 26. Slow resolution occurred in two, and eventual clearing in these was not completed until 40 days. The course of treatment was from three to 18 days and averaged 6½ days.

One patient, moribund at the time therapy was started, died shortly after the first dose of penicillin. Another patient, a man aged 59, had a pneumococcic infection which failed to respond as expected. A change to the intramuscular route of penicillin administration also failed to alter the clinical disease, and eventual, albeit gradual, improvement followed sulfadiazine therapy.

Seven patients with bronchopneumonia are included in the series. All seven had pulmonary infiltrations by roentgenogram, although solid consolidations were not seen. Bacteriologic findings were not specific. All the patients were acutely ill. Because no therapy othe

reserved for it alone. Although this entity has been known to occur in most parts of the world, no clearcut description of it appears in any of the current textbooks and references to it in the current literature, with the exception of one description in an article by Braley,[2] have failed to differentiate it sharply from other forms of nonspecific punctate epithelial or subepithelial keratitis.

THE CLINICAL ENTITY

Since 1930 twenty-six typical examples of superficial punctate keratitis have been studied by me in the states of Iowa, New York, Florida and California. In general they have presented identical clinical characteristics and have run the same course, indicating the existence of a clinical entity which may be described as follows:

Clinical Picture.—The disease is essentially epithelial keratitis characterized by multiple, discrete, epithelial

ssential lesion, however, is an intraepithelial
pacity with little if any subepithelial edema and no subepithelial infiltration. The epithelium between the opacities appears to be normal except during severe exacerbations, when there may be a minimal amount of epithelial edema between close-lying foci. In most cases the opacities are evanescent, their location varying from week to week, but in some the pattern remains relatively fixed over a period of months.

The keratitis is the most important lesion of the disease, but it may be accompanied by a mild catarrhal conjunctivitis with predominant involvement of the bulbar conjunctiva but without papillary hypertrophy or exudate. The conjunctival hyperemia increases during the periodic exacerbations of the disease but is never pronounced. Secondary bacterial infection was unknown in this series and, with a few exceptions in which scattered colonies of coagulase-positive staphylococci were found, conjunctival cultures showed a consistently normal flora. No evidence of a leukocytic reaction to the disease was derived from a study of conjunctival scrapings.

Corneal sensitivity is reduced in most instances but in varying degrees and never completely as in herpes corneae. The disease is always bilateral, even in cases seen soon after onset. The symptoms, consisting of photophobia, burning and smarting, and blurring of vision, are usually mild except during exacerbations. Visual disturbance is seldom incapacitating, but during an exacerbation in one case in this series the vision was reduced from a normal of 20/20 to 20/100 in one eye and 20/70 in the other.

No special sex incidence was noted, 15 cases occurring in males and 11 in females, and there was no grouping with respect to age, the youngest patient being a boy of 8 years and the oldest a woman of 65 years.

Clinical Course.—In this series the clinical course has been protracted in every instance, the minimum time for healing being three years. It is noteworthy that none of the patients could give a clearcut history of the time of onset. In no instance was there a history of acute onset, and in no instance was the onset associated with any significant occupational or intercurrent disease. All cases were characterized by periodic subacute exacerbations, but there seemed to be no relation between these attacks and intercurrent disease of any kind. Nasal symptoms occurred in connection with some attacks but are believed to have been due to increased tear flow into the nose rather than to an associated rhinitis. In the 8 cases which were followed to healing, no residual signs of the keratitis, such as

cicatrization or vascularization, were noted. In this respect the disease is believed to be strictly benign.

Treatment.—Superficial punctate keratitis appears to be totally resistant to treatment with the ordinary conjunctival antiseptics or with the sulfonamides used either topically or by mouth. The cases in this series were also resistant to penicillin, streptomycin, tyrothricin and aureomycin used topically. In my experience only two therapeutic measures have proved to be of any value. The first, used in four cases only, consisted in the removal of the entire corneal epithelium and the application of 3.5 per cent tincture of iodine solution to the denuded cornea. In two of the four cases healing occurred after this treatment. Application of iodine to the corneal opacities alone was ineffective. The second valuable therapeutic measure consisted in repeated smallpox vaccinations as advocated for the treatment of recurrent herpes simplex infections. In four of the nine cases with the condition treated in this way healing was complete. In the remaining 5 some degree of symptomatic relief was obtained, although the corneal disease continued to be active.

Etiological Basis.—Laboratory studies were made on 16 of the 26 patients in this series without conclusive results. In scrapings from three of the 16, scattered colonies of coagulase-positive Staphylococcus aureus were found. The bacterial flora was otherwise normal. In none of the 16 cases was a conjunctival eosinophilia or other evidence of conjunctival or corneal allergy demonstrable, and the patients reported no unusual allergic background. Conjunctival and corneal scrapings were used for rabbit cornea inoculations and in a few instances produced transient punctate corneal lesions resembling those of the human disease. In no instance, however, did chronic disease develop. Scrapings used for inoculations of mouse brain and the chorioallantois failed to produce any evidence of a virus; a few foci developed on the chorioallantois but were not transmissible in series These studies are being continued and will be the subject of a subsequent report. Braley[2] has recently reported success in isolating a virus from lesions in his cases and has produced in rabbits a chronic disease resembling the human disease. He has also reported the demonstration of neutralizing virus antibodies in serum from affected patients.

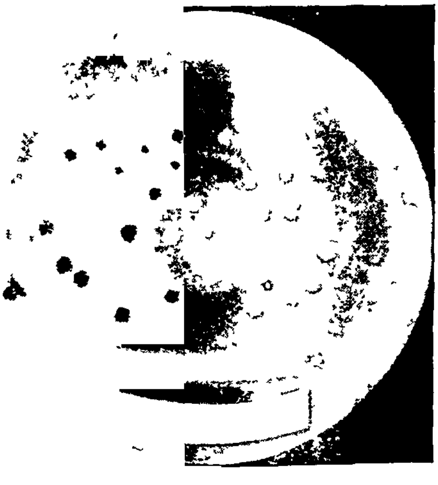

Fig 2—Large, round subepithelial opacities in a case of epidemic keratoconjunctivitis (low power magnification)

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of superficial punctate keratitis from other subepithelial and epithelial forms of superficial keratitis with punctate lesions involves the following considerations:

Subepithelial Forms.—Epidemic Keratoconjunctivitis: The classic example of a subepithelial keratitis is epidemic keratoconjunctivitis. Its diagnosis is based on the development of round subepithelial opacities (fig. 2) in seven to 10 days after onset of acute conjunctivitis. The opacities vary in size and, unlike the epithelial opacities of superficial punctate keratitis, are often grossly visible. They have a tendency to localize in the pupillary area. Epithelial changes also occur in this disease preceding the development of the subepithelial opacities, but they are microscopic in type and due primarily to epithelial edema. They have nothing in common with the larger epithelial opacities of superficial punctate keratitis. The clinical characteristics and course of epidemic keratoconjunctivitis, an acute self-limited disease of virus causation, have been adequately reported in the literature[3] and will not be redescribed here.

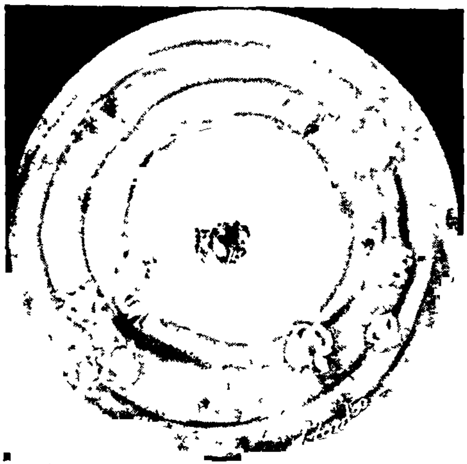

Fig 3—Subepithelial opacities in a case of herpes zoster keratitis

Nummular Keratitis: A second important type of subepithelial keratitis with punctate lesions is nummular keratitis; unlike epidemic keratoconjunctivitis, it has not been established as an etiological entity. Although the disease is apparently common on the European continent, it is seldom seen in the United States.[4] It is characterized by round, often grossly visible subepithelial opacities, similar to those of epidemic keratoconjunctivitis except for a tendency to ulcerate and form facets. Nummular keratitis is usually unilateral and exhibits neither the acute conjunctival inflammation nor the epidemic character of epidemic keratoconjunctivitis. Woods[5] has reported examples of it which were apparently due to brucellosis.

Other Diseases with Round Subepithelial Opacities: Round subepithelial opacities are seen with considerable

SUPERFICIAL PUNCTATE KERATITIS

PHILLIPS THYGESON, M.D.
San Jose, Calif.

The term superficial punctate keratitis was introduced by Fuchs[1] in 1889 to describe superficial keratitis secondary to acute conjunctivitis. This disease is now generally known under the more descriptive name of epidemic keratoconjunctivitis. Since Fuchs' original use of the term, superficial punctate keratitis has at no time been applied strictly to the disease entity he described in connection with it. It has tended rather to become a general morphological designation for any condition presenting multiple, small, discrete lesions of the cornea affecting the epithelial and immediately adjacent subepithelial tissues. This has resulted in an unfortunate confusion in the literature, since many clinical entities of known or unknown causation produce punctate epithelial lesions and a smaller but appreciable number produce punctate subepithelial lesions.

Of the many types of epithelial keratitis, however, one stands out as a distinct clinical entity, and it is proposed that the name superficial punctate keratitis be reserved for it alone. Although this entity has been known to occur in most parts of the world, no clearcut description of it appears in any of the current textbooks and references to it in the current literature, with the exception of one description in an article by Braley,[2] have failed to differentiate it sharply from other forms of nonspecific punctate epithelial or subepithelial keratitis.

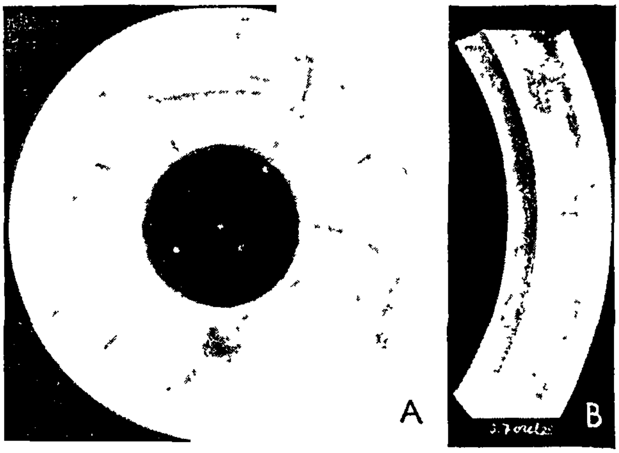

Fig. 1.—Appearance of corneal lesions in a case of superficial punctate keratitis of three years' duration. *A*, low power examination, slit lamp and corneal microscope; *B*, high power slit lamp and corneal microscope examination, showing granular nature of the opacity.

THE CLINICAL ENTITY

Since 1930 twenty-six typical examples of superficial punctate keratitis have been studied by me in the states of Iowa, New York, Florida and California. In general they have presented identical clinical characteristics and have run the same course, indicating the existence of a clinical entity which may be described as follows:

Clinical Picture.—The disease is essentially epithelial keratitis characterized by multiple, discrete, epithelial opacities (fig. 1 *A*). These lesions are relatively few in number, varying in this series of cases from three to as many as 20. They favor the pupillary area, although any part of the cornea may be involved. The individual opacities, while considerably larger than the punctate lesions of most other forms of epithelial keratitis, are still not grossly visible. The larger ones can be seen with the loupe, but use of the slit lamp is necessary for recognition of the smaller ones. Each opacity, when studied under the high power objective, can be seen to be made up of a conglomeration of smaller punctate opacities (fig. 1 *B*). The lesions stain variably with fluorescein or aqueous mercurochrome; the majority retain the stain, but some retain it either feebly or not at all. With the slit lamp the lesions are seen to be strictly epithelial and definitely nonulcerative in character, although partial desquamation of the epithelial layers may occur in the more deeply staining opacities. The essential lesion, however, is an intraepithelial opacity with little if any subepithelial edema and no subepithelial infiltration. The epithelium between the opacities appears to be normal except during severe exacerbations, when there may be a minimal amount of epithelial edema between close-lying foci. In most cases the opacities are evanescent, their location varying from week to week, but in some the pattern remains relatively fixed over a period of months.

The keratitis is the most important lesion of the disease, but it may be accompanied by a mild catarrhal conjunctivitis with predominant involvement of the bulbar conjunctiva but without papillary hypertrophy or exudate. The conjunctival hyperemia increases during the periodic exacerbations of the disease but is never pronounced. Secondary bacterial infection was unknown in this series and, with a few exceptions in which scattered colonies of coagulase-positive staphylococci were found, conjunctival cultures showed a consistently normal flora. No evidence of a leukocytic reaction to the disease was derived from a study of conjunctival scrapings.

Corneal sensitivity is reduced in most instances but in varying degrees and never completely as in herpes corneae. The disease is always bilateral, even in cases seen soon after onset. The symptoms, consisting of photophobia, burning and smarting, and blurring of vision, are usually mild except during exacerbations. Visual disturbance is seldom incapacitating, but during an exacerbation in one case in this series the vision was reduced from a normal of 20/20 to 20/100 in one eye and 20/70 in the other.

No special sex incidence was noted, 15 cases occurring in males and 11 in females, and there was no grouping with respect to age, the youngest patient being a boy of 8 years and the oldest a woman of 65 years.

Clinical Course.—In this series the clinical course has been protracted in every instance, the minimum time for healing being three years. It is noteworthy that none of the patients could give a clearcut history of the time of onset. In no instance was there a history of acute onset, and in no instance was the onset associated with any significant occupational or intercurrent disease. All cases were characterized by periodic subacute exacerbations, but there seemed to be no relation between these attacks and intercurrent disease of any kind. DIFFERENTIAL DIAGNOSIS

The differential diagnosis of superficial punctate keratitis from other subepithelial and epithelial forms of superficial keratitis with punctate lesions involves the following considerations:

Subepithelial Forms.—Epidemic Keratoconjunctivitis: The classic example of a subepithelial keratitis is epidemic keratoconjunctivitis. Its diagnosis is based on the development of round subepithelial opacities (fig. 2) in seven to 10 days after onset of acute conjunctivitis. The opacities vary in size and, unlike the epithelial opacities of superficial punctate keratitis, are often grossly visible. They have a tendency to localize in the pupillary area. Epithelial changes also occur in this disease preceding the development of the subepithelial opacities, but they are microscopic in type and due primarily to epithelial edema. They have nothing in common with the larger epithelial opacities of superficial punctate keratitis. The clinical characteristics and course of epidemic keratoconjunctivitis, an acute self-limited disease of virus causation, have been adequately reported in the literature[3] and will not be redescribed here.

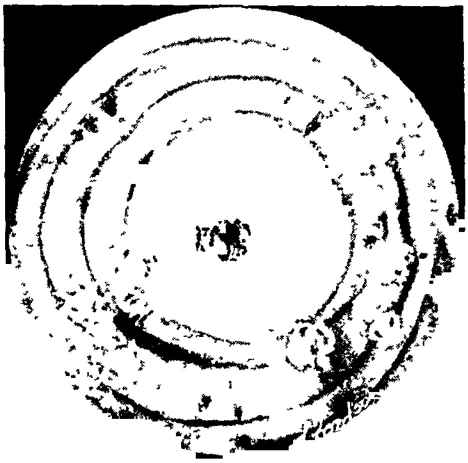

Fig. 3—Subepithelial opacities in a case of herpes zoster keratitis.

Nummular Keratitis: A second important type of subepithelial keratitis with punctate lesions is nummular keratitis; unlike epidemic keratoconjunctivitis, it has not been established as an etiological entity. Although the disease is apparently common on the European continent, it is seldom seen in the United States.[4] It is characterized by round, often grossly visible subepithelial opacities, similar to those of epidemic keratoconjunctivitis except for a tendency to ulcerate and form facets. Nummular keratitis is usually unilateral and exhibits neither the acute conjunctival inflammation nor the epidemic character of epidemic keratoconjunctivitis. Woods[5] has reported examples of it which were apparently due to brucellosis.

Other Diseases with Round Subepithelial Opacities: Round subepithelial opacities are seen with considerable frequency in the keratitis of herpes zoster ophthalmicus (fig. 3) and occasionally in phlyctenular keratitis.[6] With respect to these two diseases there is no problem in differential diagnosis because of the characteristic skin lesions of the former and the characteristic conjunctival lesions of the latter. To my knowledge there are no other forms of subepithelial keratitis which enter into the problem of differential diagnosis under discussion.

Fig 4.—Distribution of lesions of various types of epithelial keratitis

Epithelial Forms.—It is only the epithelial forms of keratitis which present any difficulty in the differential diagnosis of superficial punctate keratitis. Epithelial changes, as seen with the slit lamp and corneal microscope in the various forms of epithelial keratitis other than superficial punctate keratitis, appear at first glance to be completely nonspecific in character. However, on closer observation morphological differences and differences in distribution can be discerned.

The commonest epithelial lesion is a microscopic pointlike opacity, stainable with fluorescein, which is probably a minute round epithelial erosion produced by epithelial cell desquamation. This desquamation appears to involve only the upper layers of the epithelium, as judged by its examination under high power magnification, and is the type seen so frequently in association with staphylococcic blepharoconjunctivitis. A second distinguishable lesion is similar to the first except that instead of being round it is irregular in shape, linear or comma shaped. This type of lesion is seen characteristically in keratitis sicca. A third morphological type is an intraepithelial opacity which may be punctate or amorphous and is frequently confluent. Fluorescein staining is irregular, some lesions not staining at all and others staining faintly. This is the type seen characteristically in the prexerosis of early vitamin A deficiency. Linear erosions suggest trauma, as from trichiasis. Widespread, diffuse, blotchy epithelial erosion is characteristic of exposure keratitis. Epithelial filaments are of course characteristic of filamentary keratitis which is usually but not always an advanced form of keratitis sicca. A combination of several different types of lesion may exist simultaneously in the same case. As seen in figure 4, the distribution of the lesions also has important differential significance.

In my experience 11 different types of epithelial keratitis have appeared to be differentiable from superficial punctate keratitis on clinical and etiological grounds, as follows:

1. Epithelial Keratitis Secondary to Staphylococcic Blepharoconjunctivitis: This is by far the most commonly encountered type and can usually be readily diagnosed clinically on the basis of the associated staphylococcic blepharoconjunctivitis. It appears typically as multiple, minute, fluorescein-staining points involving the lower third of the cornea (fig. 5 *A*). The staining points appear to be minute epithelial erosions and are only a fraction of the size of the lesions of superficial punctate keratitis. Although ordinarily rather evenly spaced, they occasionally group themselves in clusters which simulate the lesions of superficial punctate keratitis. This occurs only rarely, however, and has not complicated the problem of differential diagnosis since the microscopic epithelial erosions typical of staphylococcic keratitis are always also present.

2. Epithelial Keratitis Secondary to Pneumococcic and Koch-Weeks Conjunctivitis: The epithelial lesions which occur occasionally in pneumococcic and Koch-Weeks conjunctivitis sometimes simulate closely those occurring in superficial punctate keratitis but never have been a diagnostic problem. They have always been transient, disappearing with the healing of the primary conjunctivities.

3. Epithelial Keratitis Secondary to Seborrheic Blepharitis: This rather rare clinical entity has been seen only exceptionally in association with severe forms of seborrheic blepharitis[7] and may be an allergic manifestation of sensitivity to Pityrosporum ovale. The majority of cases of seborrheic blepharitis, when not complicated by secondary staphylococcic infection, have no associated keratitis. In my experience seborrheic keratitis has appeared as an epithelial keratitis involving the entire corneal surface (fig. 5 *B*). The changes have consisted in punctate and irregular blotchy fluorescein-staining erosions, usually severe enough noticeably to affect vision. They have cleared simultaneously with clearing of the blepharitis.

4. Epithelial Keratitis in Trachoma: Minute, punctate, fluorescein-staining epithelial erosions are a characteristic feature of trachoma (fig. 6). They are seen at the onset of the disease, simultaneously with the development of conjunctival lesions and before the development of pannus, and may be the last lesion

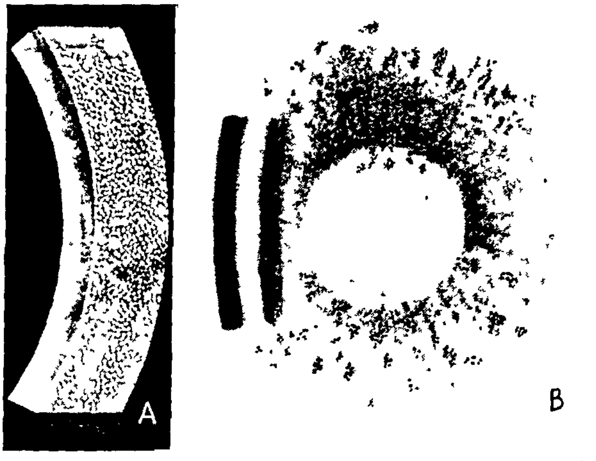

Fig 5.—*A*, punctate fluorescein staining epithelial keratitis secondary to staphylococcic blepharoconjunctivitis; *B*, epithelial keratitis in a severe case of seborrheic blepharitis of long duration

to disappear. Microscopic in type, they can be seen only with the slit lamp and corneal microscope. Their distribution may be considered characteristic in that the upper half of the cornea, particularly the upper limbus region, is usually predominantly involved.

5. Epithelial Keratopathy in Keratoconjunctivitis Sicca: Mild forms of keratitis sicca are characterized by punctate, fluorescein-staining erosions of the corneal epithelium, similar in appearance and distribution to the forms seen in staphylococcic epithelial keratitis. When loss of tear function is severe, however, the epithelial changes become widespread, irregular and blotchy, and may be accompanied with filament formation (fig. 7).

6. Epithelial Changes in Neurotrophic and Exposure Keratitis: In mild cases the epithelial changes in neurotrophic and exposure keratitis are punctate in character, involve the lower third of the cornea predominantly and appear to be related most often to drying of the cornea due to exposure while sleeping. Severe cases show widespread, diffuse, blotchy staining. Closure of the eye effects disappearance of the lesions in mild cases and improvement in severe cases.

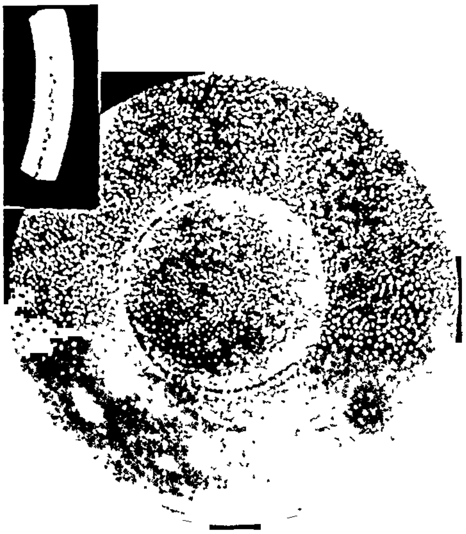

Fig. 6.—Microscopic, fluorescein staining epithelial keratitis in a case of acute trachoma at onset. Atypically, the pupillary area is predominantly involved.

7. Epithelial Keratitis in Vernal Catarrh: Mild forms of vernal catarrh ordinarily exhibit no corneal changes, but in severer cases, both palpebral and limbal, epithelial changes are common. They have been described by Tobgy,[8] under the name keratitis epithelialis vernalis, as appearing as though the cornea were dusted with flour. Tobgy noted edema of the epithelium and occasional vesicle formation, stating that the changes were most frequently to be seen in the upper half of the cornea and in the periphery of the cornea in the bulbar type of the disease but that occasionally the whole cornea was affected.

In my experience keratitis epithelialis vernalis (Tobgy) (fig. 8) has been found in almost every case of vernal catarrh, at least during exacerbations, although the involvement has in some instances been minimal. The epithelial changes are sufficiently characteristic to be almost pathognomonic of the disease. They consist of an intraepithelial opacification which, instead of being typically punctate in character, usually appears as a syncytium dotted with minute clear areas. In limbal cases the lesion appears principally in the area of the lid aperture, but in palpebral cases the upper half of the cornea is more often involved.

8. Epithelial Changes in Prexerosis: One of the earliest signs of prexerosis is a punctate opacification of the corneal epithelium believed to be due to beginning cornification of the epithelial cells as a result of vitamin A deficiency. In my experience it has appeared simultaneously with the development of Bitot spots at the temporal limbus and has been seen in children on deficient diets and in chronic alcoholic adults with polyvitamin deficiency. The epithelial changes resemble those of vernal catarrh except that the whole corneal surface is characteristically involved. Unlike other forms of epithelial keratitis, e. g., staphylococcic keratitis, epithelial desquamation does not seem to be a major feature and fluorescein-staining is minimal.

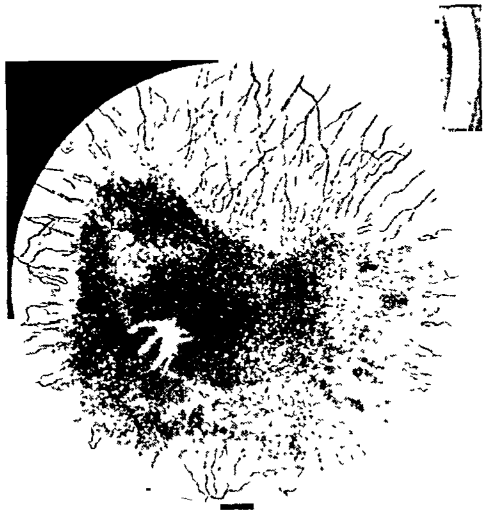

Fig. 8.—Keratitis epithelialis vernalis (Tobgy) in a severe case of palpebral vernal catarrh.

9. Epithelial Keratitis in Ultraviolet and Roentgen Ray Burns: Punctate epithelial keratitis[9] is a feature of radiation burns, e. g., the keratitis of flash burns which produces photophobia and blepharospasm. This

[9] Scobee, R. G., and Griffey, E. W.: Actinic Keratoconjunctivitis, Am. J. Ophth. 27: 632 (June) 1944.

keratitis involves the central area of the cornea not protected by the lids and appears as a punctate, fluorescein-staining keratitis with edema and spotty desquamation of the epithelial cells. The epithelial changes seen in connection with a few roentgen ray and radiation burns of the cornea have been identical.

10. Epithelial Keratitis in Molluscum Contagiosum and Verruca Keratitis: A pu[illegible] epithelial keratitis, identical [illegible] epithelial keratitis seen in trachoma, was a constant feature of 8 cases of molluscum keratoconjunctivitis that I observed. As in trachoma, the keratitis favored the upper half of the cornea, even when the molluscum nodule was on the lower lid. Removal of the nodule resulted in rapid cure of the keratitis.

The epithelial keratitis associated with the common wart has been entirely different. In cases observed by me it has been localized to one or more small areas and the changes have been not punctate but blotchy and irregular, resembling recurrent erosion of the cornea. Cure of the keratitis has always followed removal or destruction of the lid margin tumor.

11. Occupational and Traumatic Epithelial Keratitis: As pointed out by Davidson,[10] the lesion resulting from injury with multiple minute foreign bodies, such as may be sustained by stone masons, grinders and other occupational specialists, may suggest superficial punctate keratitis, but careful slit lamp observation quickly reveals the true nature of the opacities. Workers in the artificial silk industry, and in other industries in which exposure to irritating chemical vapors occurs, have been known to manifest punctate epithelial changes.[11] In the few industrial cases of this nature that I have seen, the epithelial lesions stained readily with fluorescein and appeared to be desquamative in character. Their distribution conformed to the area of the lid aperture. Traumatic epithelial keratitis due to trichiasis can usually be recognized readily by the linear character of the fluorescein-staining streaks.

COMMENT

The present confusion with respect to the terminology of punctate lesions of the corneal epithelium and immediately subjacent tissues is unfortunate for several reasons. It has reduced the value of published reports on superficial keratitis, especially in the foreign literature, and in this country has made the teaching of the various forms of superficial corneal disease unnecessarily difficult. Finally, the lack of a clearcut differentiation of one form of superficial keratitis from another has interfered with the administration of appropriate treatment on many occasions because of confusion as to etiological basis and clinical course. The classification of punctate forms of superficial keratitis suggested in this report is an attempt to bring a degree of order to present knowledge of this group of clinical and etiological entities.

As designated in this report, superficial punctate keratitis itself is a readily definable entity whose name aptly describes it. As a matter of fact, there are few corneal diseases whose morphological and clinical characteristics can be as well defined and in which differential diagnosis offers so little difficulty. It is only unfortunate that the name was originally introduced for an entirely different disease, which is now much better described by its currently accepted name, epidemic keratoconjunctivitis.

Of the two principal subepithelial forms of keratitis with punctate lesions, only nummular keratitis remains a diagnostic problem. It has not yet been established as an etiological entity, and its characteristics are ill defined. The epithelial forms of punctate keratitis, on the other hand, are all susceptible to definition and many are secondary to well defined diseases of the conjunctiva and lid margins. The therapeutic value of identifying precisely all cases of epithelial keratitis would seem to be obvious; the treatment of staphylococcic epithelial keratitis, for example, has nothing in common with the treatment of keratitis sicca.

SUMMARY AND CONCLUSIONS

1. The term superficial punctate keratitis, introduced by Fuchs in 1889 to describe the disease now known as epidemic keratoconjunctivitis, has been applied indiscriminately in the literature to any epithelial or subepithelial form of keratitis with multiple, small, discrete lesions, without regard to etiological basis or clinical definition.

2. Among the many types of epithelial and subepithelial keratitis of varied causation, there is one distinct clinical entity for which the name superficial punctate keratitis seems ideally suited. It is an epithelial keratitis of long duration which is always bilateral, is associated with minimal conjunctival symptoms, runs a benign course and is probably caused by a virus.

3. Other forms of superficial keratitis can be classified according to etiological factors or clinical characteristics. Epidemic keratoconjunctivitis and nummular keratitis are the principal examples of subepithelial keratitis; examples of epithelial keratitis include the types secondary to staphylococcic blepharitis, seborrheic blepharitis, trachoma, molluscum contagiosum conjunctivitis, vernal catarrh, prexerosis, keratoconjunctivitis sicca, lagophthalmos, loss of corneal sensation and occupational traumatisms.

ABSTRACT OF DISCUSSION

Dr. James H. Allen, New Orleans: Dr. Thygeson has again clarified a situation which is extremely confusing in the literature. He has emphasized the diagnostic features of superficial punctate keratitis, but probably this paper is more important because it calls attention to the etiological factors of epithelial keratitis. It has been my impression for a number of years that ophthalmologists have overlooked the extraocular or extracorneal factors of epithelial keratitis, since many corneal lesions have been treated locally for a prolonged period without benefit, and when finally attention has been paid to the extracorneal factors the lesion has healed. Some years ago associates and I were privileged to repeat and elaborate the experiments made by Morax and Elmassian in 1898. They instilled crude bacterial filtrates onto eyes and produced conjunctivitis and epithelial keratitis. We were able to prove that the lesion was due to toxin in the case of staphylococcic filtrates. Similar lesions occurred with filtrates from nontoxigenic organisms such as the Pneumococcus and were due to proteolytic enzymes produced by those organisms. Therefore we must consider the possibility of keratitis being produced by infection of the conjunctiva, lid margin and even the adjacent skin. In these instances, treatment of the corneal lesion is of no benefit but elimination of the adjacent infection will result in rapid healing. Dr. Thygeson referred to the keratitis produced by tumors, warts and molluscum of the lid margin. These may be mechanical or infectious, but excision of the tumor results in improvement of the corneal lesion. Many of these have been overlooked and the corneal lesion treated without benefit until the tumor has been removed. An exposure type of keratitis occurs in vernal conjunctivitis. The condition Dr. Thygeson described occurs most commonly with large papillomatous lesions of the lid, whereas in the limbic type of vernal conjunctivitis the lesion has been around the margin of the cornea rather than in the central band. Therefore I have thought of two varieties of epithelial keratitis in association with vernal conjunctivitis. I should like to emphasize the importance of study of the precorneal film in the recognition of causes of epithelial lesions of the cornea; by close examination of the precorneal film one can make a diagnosis of keratitis sicca before especially pronounced changes have occurred in the corneal epithelium. Another punctate epithelial lesion is that produced by anesthetics and detergents. Several years ago Dr. Swan warned of the danger of the prolonged use of detergents on the conjunctiva. The detergent probably destroys the protective precorneal film, thus permitting drying of the epithelium in addition to causing direct damage to the cells. Dr. Thygeson has rendered a service in clarifying the differential diagnosis of these lesions.

[11] Rankine, D.: Artificial Silk Keratitis, Brit. M. J. **2**: 6 (July 4) 1936.

Dr. A. E. Maumenee, San Francisco: I would like to congratulate Dr. Thygeson on the clearcut definition of the disease he has called superficial punctate keratitis. There has been considerable confusion in the literature about this disease because of the multitude of names which have been given it, e. g., superficial punctate keratitis, keratitis epitheliolysis and recurrent punctate erosion of the corneal epithelia. This type of confusion not infrequently occurs when a descriptive and not an etiological name is given to a condition. I would like to ask Dr. Thygeson whether punctate epithelial keratitis or punctate epithelial erosion keratitis would not be a more descriptive name of the condition he has just described than the term superficial punctate keratitis. It is always difficult to give a complete list of differential diagnoses. I would like to add a few more conditions to those that Drs. Thygeson and Allen have mentioned. Allergic reactions to atropine and other drugs can cause a superficial punctate erosion of the corneal epithelium. A similar reaction also occurs occasionally in the early stages of herpes simplex. Pure neuroparalytic keratitis without chronic exposure of the globe may produce epithelial erosion. In some cases recurrent erosion of the corneal epithelium following a fingernail scratch or like injury may cause punctate epithelial lesions. Lagophthalmos which occurs during sleep in some patients may produce a similar lesion in the lower part of the cornea. I agree that some of the chronic, persistently incapacitating lesions should be treated by removing the corneal epithelium after the application of iodine. I have had good results with this method of therapy in two patients. The immunobiologic basis of repeated vaccine therapy has always been puzzling to me. I wonder whether Dr. Thygeson has any suggestions on why repeated vaccination, even though there is a negative skin reaction, should be of value when there has been previous immunization. Also, does Dr. Thygeson have any comments on histamine desensitization as described by Horton and Walsh for these cases?

Dr. Phillips Thygeson, San Jose, Calif.: I am glad to learn of the additional types of epithelial keratitis suggested by Drs. Allen and Maumenee. With regard to terminology, the disease discussed in this paper has been known as superficial punctate keratitis, at least in the United States for many years, and I was under the impression that it was the same disease as that described by Fuchs until the first occurrence in this country in 1941 of epidemic keratoconjunctivitis. A review of the literature then showed that Fuchs's description applied to this disease rather than to any form of epithelial keratitis. Since the clinical entity under consideration in this paper has been known as superficial punctate keratitis I think it would be wise to maintain that name, which describes it well, and in addition to restrict use of that name to this entity instead of using it also to refer to other types of epithelial keratitis. With regard to vaccine therapy, the dermatologists introduced repeated vaccinia virus vaccinations for the treatment of recurrent herpes simplex infection. There is some immunologic basis for such treatment in the interference phenomenon, in which a pantropic virus is able to crowd out other less active viruses. In any event, I am convinced that vaccine therapy has been of some value in superficial punctate keratitis, but I do not know whether the effect was due to the interference phenomenon or to a foreign portein reaction. Foreign protein given in the form of typhoid vaccine, however, did not help my patients. I have been interested in the use of histamine desensitization in corneal disease but have had too little experience with this treatment to discuss it. I think it should receive further investigation.

ALUMINUM GELS IN THE MANAGEMENT OF RENAL PHOSPHATIC CALCULI

EPHRAIM SHORR, M.D.
and
ANNE C. CARTER, M.D.
With the Technical Assistance of Vincent Toscani, Viola Davis and Estelle Stevens
New York

Of the commoner types of renal calculi, the phosphatic variety remains one of the most difficult to manage, as regards both the prevention of recurrences after operative removal and the inhibition of the further growth of stones in situ. Although the reported incidence of recurrence varies widely, it can be fairly estimated to be approximately 40 per cent, on the basis of several of the more recent compilations.[1]

A number of factors apparently contribute to this high recurrence rate, quite apart from the difficulty in completely removing the entire mass of calculi at operation. Of major importance is the coexistence of urinary tract infection with organisms which are difficult to eliminate permanently even with modern chemotherapy.[2] In addition to the pathological effects of bacterial infection on the renal pelvis, the urea-splitting properties possessed by the most frequent bacterial offenders result in a highly ammoniacal urine favorable to the precipitation of calcium and phosphate ions. Anatomic or pathological obstructions to urine flow are also frequently associated with phosphatic stones and predispose to their reformation by stasis. In a small number of patients phosphatic calculi arise from systemic metabolic disturbances which may escape ready diagnosis or may resist correction or arise from inadvertent complications of treatment for other conditions. The former include hyperparathyroidism and enforced immobilization, such as that after spinal injury. The commonest examples of treatment regimens causing inadvertent complications are certain types of alkalinizing therapy for peptic ulcer or for the prevention of renal stones of the uric acid or cystine type.

The treatment usually employed in the management of phosphatic calculi is the acidification of the urine by means of acid-ash diets or acidifying agents in order to take advantage of the greater solubility of calcium and phosphate ions in the acid range.[3] Unfortunately this therapeutic approach is distinctly limited in effectiveness in many cases and particularly in those of

the more malignant type.[4] The chief limiting factors are (*a*) the presence of bacterial infection with ammonia-forming organisms, which renders useless any acidifying regimen, and (*b*) the frequent coincidence of impaired renal function, which makes such a regimen hazardous by exposing the patient to the dangers of acidosis and further renal functional impairment.

In a previous report from this laboratory attention was called to the possible usefulness of a new therapeutic regimen whose effectiveness was not similarly limited.[5] This consisted in the use of aluminum hydroxide gels to bring about appropriate alterations in the chemical composition of the urine so that it would be unfavorable for the precipitation of phosphate ions. The rationale for this regimen resides in the formation of insoluble aluminum phosphate salts in the intestinal tract and the corresponding reduction in the amount of phosphorus available for absorption. This diversion of phosphate excretion via the intestinal route results in a proportional diminution in the amount excreted in the urine. With appropriate reduction in the concentration of phosphate ions, a point should be reached at which precipitation of this ion, along with calcium, ammonia or magnesium, could take place with difficulty or not at all, regardless of the urinary p_H. In the presence of impaired renal function, hyperphosphatemia and hypocalcemia, this regimen has been shown to have the additional advantage of correcting these electrolyte aberrations, often with improvement in the renal function.[6] Furthermore, its continued use is unassociated with any decrease in alkali reserve.

The limited therapeutic experience which was available at the time of the original report has now been amplified, with respect to both the number of patients under study and the duration of therapy. It is the purpose of the present report to summarize and evaluate this experience. Although the number of patients under study is still too small to permit definitive conclusions, the results to date with this regimen have been sufficiently impressive to warrant its recommendation. It is hoped that these observations will stimulate the more extensive use of this therapeutic procedure and thereby facilitate the conclusive evaluation of its merits.

MATERIALS AND METHODS

The group under study comprised 22 patients, 16 men and 6 women, whose phosphatic stone histories are given in detail below. They have been under observation and treatment in the Endocrine Clinic of the New York Hospital for two to seven years; 15 of them have also been studied on the Metabolism Ward of the Russell Sage Institute of Pathology. Included in this series is one hyperparathyroid patient with bilateral renal stones.

The patients studied on the Metabolism Ward were placed on constant diets, as indicated in each experiment. Calculated values for the various foods were obtained largely from the sixth edition of Sherman.[7] Twenty-four-hour urine samples were collected with toluene or thymol as preservative, and creatinine determinations by the method of Folin were made on all specimens to establish the completeness of the urine collections.

The urinary phosphorus was determined by the method of Fiske and SubbaRow, calcium by the method of Shohl and Pedley and the p_H with a hydrogen ion meter. All blood serum specimens were obtained while the patient was in the fasting state, except as otherwise noted, and analyzed for calcium by the method of Clark and Collip, for phosphorus by the method of Fiske and SubbaRow, for proteins by the Kjeldahl method and for alkaline phosphatase by the method of Gutman (personal communication).

The patients were followed in the Endocrine Clinic with monthly or bimonthly urinary phosphorus, calcium and creatinine determinations; roentgenograms of the kidneys, urine analyses and cultures, and estimations of fasting serum calcium, phosphorus, protein and alkaline phosphatase were performed at frequent intervals. To avoid the variations in aluminum gels resulting from different manufacturing processes, the following preparations from one source were utilized throughout: amphojel,® amphojel® tablets, amphojel® with magnesium trisilicate (contains 12 per cent magnesium trisilicate) and basaljel® (basic aluminum carbonate gel). All were administered in equally divided doses one hour after meals and at bedtime.

The range of daily dosage for each aluminum gel preparation was as follows: amphojel® and amphojel® with magnesium trisilicate, 90 to 200 cc., amphojel® tablets, 40, and basaljel,® 80 to 180 cc. The constipating effects of the different aluminum gel preparations varied from patient to patient and from time to time in the same patient. Constipation, when present, was controlled by cathartics of the patient's choice, such as mineral oil (liquid petrolatum), cascara or milk of magnesia (magnesia magma) in amounts sufficient to insure a daily bowel movement; as a result, no instance of fecal impaction was encountered in the patients taking these large amounts of aluminum gels.

To assist the ambulatory patient in the selection of an appropriate diet, a sample menu was constructed. This provided between 1,200 and 1,300 mg. of phosphorus a day and approximately 700 mg. of calcium; it was adequate with respect to other nutritional and vitamin requirements. The patients were instructed in its use by a staff dietitian. In addition, the patients were given a diet sheet detailing foods that were permissible and those which should be excluded because of an excessive phosphorus content.

RESULTS

1. *Comparison of Effectiveness of Various Aluminum Gel Preparations in Reducing Urinary Phosphorus.*—The reduction in urinary phosphorus excretion by the administration of aluminum gels is dependent on three factors: the phosphorus intake, the type of aluminum gel and the amount administered. The influence of each of these factors was studied with patients maintained under controlled conditions in the Metabolism Ward. The dietary phosphorus intake of each patient was constant throughout, the absolute amounts being varied for different patients. Dosage and type of aluminum gel preparations were also varied in order to provide data on their relative effectiveness in reducing urinary phosphorus.

Attention was centered on the effectiveness of two aluminum gels, amphojel® and basaljel®, prepared by different procedures.[8] The latter preparation, which had an aluminum content of 2.65 Gm. per 100 cc. as compared with 2.12 Gm. in the standard amphojel,® was developed with the cooperation of the staff members of Wyeth, Inc. In addition to its somewhat higher aluminum content, basaljel® seemed to offer a theoretical advantage over the aluminum hydroxide gels for the purpose of this study; the aluminum carbonate type of gel is more likely, during its contact with the hydrochloric acid of the gastric juice, to have its aluminum made more completely available for phosphate precipitation in the intestinal tract. This potential superiority was borne out by the metabolic studies.

[7] Sherman, H. C.: Chemistry of Food and Nutrition, ed. 6, New York, the Macmillan Company, 1941.

[8] These aluminum gel preparations were supplied by Wyeth, Inc. Mr. Alfred Barol and Dr. David Ashkenaz of Wyeth, Inc., assisted in these studies in many ways.

Figure 1 illustrates four such comparative studies; each patient received a constant diet. In those with normal renal function (R. C., H. R. and E. L.), the aluminum carbonate gel was approximately one third more effective by volume than the aluminum hydroxide gel in reducing the urinary phophorus. Patient F. M. had appreciable impairment of renal function (blood urea nitrogen 30 mg. per 100 cc.; maximal urea clearance 43.7 per cent; phenolsulfonphthalein clearance 34 per cent in two hours, and maximal concentration 1.010); in this patient basaljel[5] proved to be 50 per cent more efficient than amphojel.[6] It was possible to reduce profoundly the urinary phosphorus excretion in patient E. L., who had hyperparathyroidism with renal calculi. However, the response is not as uniform in patients with this disease as in the normal subject, and the lowering of the urinary phosphorus with a given dosage of aluminum gel is likely to be less pronounced. Thus, in one subject with hyperparathyroidism associated with bone lesions but without renal calculi and with an initial low serum inorganic phosphorus value of 1.9 mg. per 100 cc., the urinary phosphorus output was reduced to 300 mg. per 24 hours while the subject was receiving 200 cc. of amphojel® a day, an amount that would virtually abolish urinary phosphorus excretion in the normal person on the same phosphorus intake.

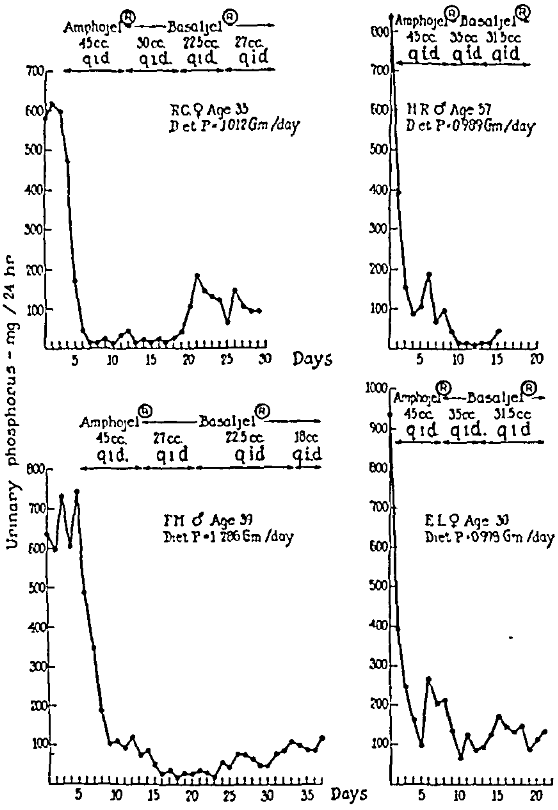

Fig 1.—Relative effectiveness of amphojel[8] and basaljel[5] in various doses given four times a day in reducing urinary phosphorus excretion in patients with renal calculi. Patient F. M. had renal insufficiency and E. L., hyperparathyroidism

The convenience of aluminum hydrate tablets for the ambulatory patient prompted a comparison of this type of preparation with the liquid form (see fig. 2). This revealed a discrepancy between the acid-buffering properties of this preparation and the capacity to reduce urinary phosphorus excretion. On the basis of the antacid action, 25 cc. of amphojel[8] is equivalent to three tablets of the drug (0.6 Gm. tablets, each containing 0.2 Gm. of aluminum), whereas approximately one and one-half times the calculated number of tablets were found to be required to achieve results equivalent to those with the aqueous suspension with respect to urinary phosphorus excretion.

With the reduction of urinary phosphorus brought about by the administration of the aluminum gels, there may be a slight and generally transient increase in the urinary calcium, as illustrated in figure 3. The rise in urinary calcium rarely exceeds 100 mg. per 24 hours and is small in comparison with the concurrent fall in urinary phosphorus. An example is given below in the case report of patient J. C. of the effects of prolonged aluminum gel administration on the urinary calcium; no appreciable rise has occurred after as long as five years of this therapy.

No changes of consequence were observed in the urinary p_H, the fasting serum calcium, protein or alkaline phosphatase levels during aluminum gel therapy, nor did amphojel® with magnesium trisilicate, in doses of 90 to 200 cc. per day for a period of six months, produce any significant change in the carbon dioxide content of the serum in the 13 subjects studied.

The effect of the level of phosphorus in the diet on urinary phosphorus output during aluminum gel therapy is readily demonstrable and can be shown to constitute a major factor in the irregular excretion of urinary phosphorus during aluminum gel therapy in the ambulatory patient. The stoechiometric relation between phosphorus intake and aluminum gel dosage with respect to aluminum phosphate precipitation in the intestinal tract emphasizes the necessity for the standardization of each factor in the individual patient and for the detection of any deviations from the prescribed regimen by frequent 24-hour urinary analyses for phosphorus.

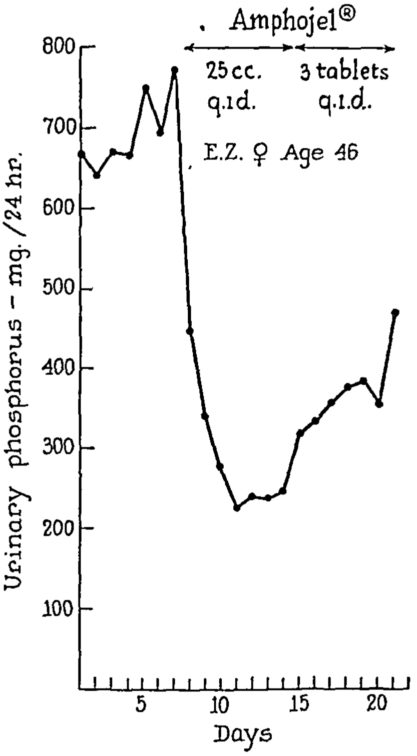

Fig. 2.—Relative effectiveness of amphojel[8] given four times a day as *aqueous suspension and as tablets in reducing* urinary phosphorus excretion (phosphorus intake constant at 1.237 Gm.).

2. *Mechanisms Involved in the Reduction of Urinary Phosphorus by Aluminum Gels.*—The mechanism by which the low urinary phosphorus excretion is brought about during aluminum gel therapy is a matter of interest. The studies of Freeman and Freeman[6] on children with renal insufficiency showed this agent to cause a striking reduction in serum inorganic phosphorus concurrent with the reduction of the urinary inorganic phosphorus excretion. In their series one child who had osteopetrosis but good renal function also showed a pronounced fall in fasting inorganic phosphorus with aluminum hydroxide therapy while on a low phosphorus diet.

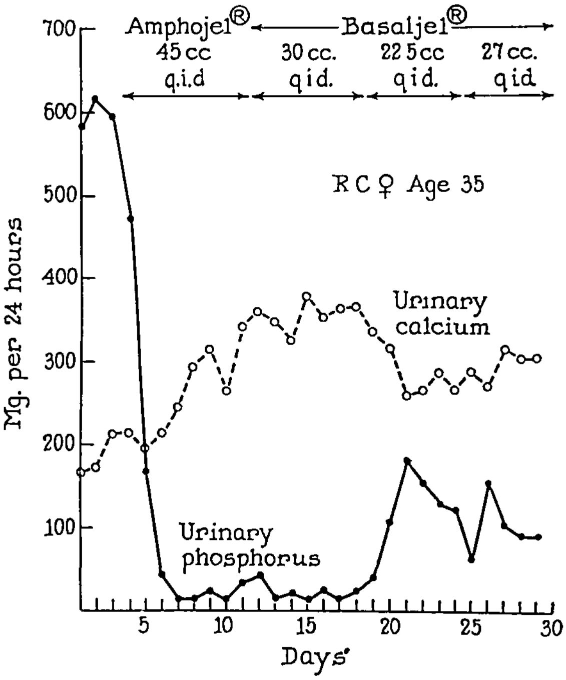

Fig 3.—Effects of amphojel® and basaljel® in various doses given four times a day on urinary phosphorus and calcium excretion on a constant diet. The diet contained: phosphorus, 1.012 Gm.; calcium, 0.489 Gm., and nitrogen, 10.48 Gm., per day.

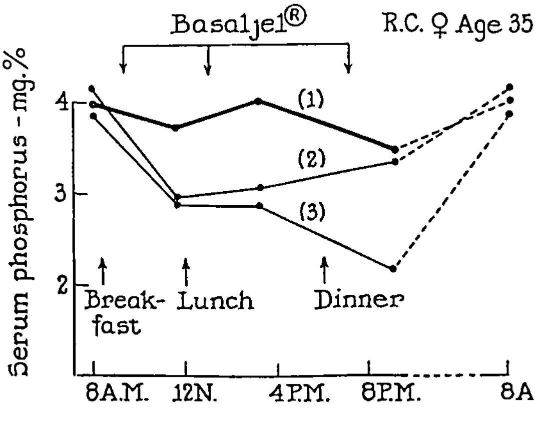

Fig. 4.—Alterations in serum inorganic phosphorus during basaljel® therapy in a patient on a constant phosphorus intake of 1.012 Gm. per day: curve 1, control, curve 2, basaljel® 27 cc. four times a day, and curve 3, basaljel® 30 cc. four times a day. The 24 hour urinary phosphorus during experiment 1 was 0.597 Gm.; during experiment 2 it was 0.092 Gm., and during experiment 3 it was 0.015 Gm. (From an unpublished study with Drs. Richmond W. Smith Jr. and William C. Thomas Jr.)

In the group of adults included in the present study a slight but irregular reduction in the average values for serum inorganic phosphorus did occur during aluminum gel therapy, but in most instances the fasting values were not significantly altered despite the continued low urinary phosphorus output (table 1). The possibility was explored that a greater reduction in the serum inorganic phosphorus values than was observed in the fasting state might prevail during the period of the day over which the aluminum gel was being taken. This proved to be the case. Figure 4 shows the results of one such study in a patient maintained on a constant dietary intake before and during aluminum gel therapy. The observations in this case are representative of four others studied; they serve to show that the serum inorganic phosphorus values are significantly lowered during the greater portion of the 24 hours over which an aluminum gel preparation is taken. The fasting values are therefore not a reliable indication of the prevailing serum inorganic phosphorus levels. The differences between the serum inorganic phosphorus curves during the control and aluminum gel periods could not be attributed to changes in blood sugar values, which were of the same order during each test. These lowered serum inorganic phosphorus values assuming that the patient had an unaltered glomerular filtration rate, would provide a smaller load of inorganic phosphate to the renal tubules and allow for its correspondingly more complete tubular resorption. Hence, the same mechanism would appear to operate in subjects with normal renal function as was shown to be involved by Freeman and Freeman in children with the hyperphosphatemia of renal disease. In one patient of this series, with renal insufficiency, there was a prompt fall in fasting serum inorganic phosphorus of 0.9 mg. per 100 cc. on which was superimposed a further reduction during the portion of the day over which he received aluminum gel.

Table 1.—*Effects of Aluminum Gel Therapy on Fasting Serum Inorganic Phosphorus Values*

Patient	Duration of Therapy in Years	Prior to Therapy: Average Serum P, Mg./100 Cc.	Prior to Therapy: No. of Determinations	With Aluminum Gel Therapy: Average Serum P, Mg./100 Cc.	With Aluminum Gel Therapy: No. of Determinations	Average Change in Serum P with Therapy, Mg./100 Cc.
H. F.	3	3.97 (3.45 to 4.34)	4	3.29 (2.72 to 3.98)	4	−0.68
F. M.	2	2.81 (2.78 to 2.84)	2	2.24 (1.61 to 3.00)	9	−0.57
J. M.	3	4.22 (3.60 to 5.0)	8	4.55 (3.76 to 5.97)	6	+0.33
J. M.	7	4.18 (3.89 to 4.38)	12	3.67 (3.07 to 4.32)	16	−0.51
D. R.	3	3.90 (3.62 to 4.40)	7	3.66 (3.32 to 4.28)	3	−0.24
I. S.	6	3.32 (3.32)	2	3.05 (2.62 to 3.44)	8	−0.27
L. T.	7	4.01 (3.55 to 4.65)	7	3.63 (2.72 to 4.48)	14	−0.41
M. T.*	6	3.43 (3.21 to 3.78)	3	3.41 (2.53 to 4.76)	9	−0.02

* Case 1 in this article

Another possible mechanism by which the aluminum gels might reduce the urinary inorganic phosphorus is suggested by the current concepts that the parathyroid hormone influences urinary phosphorus excretion by reducing the renal tubular resorption of phosphate and that the extent of parathyroid hormone secretion is regulated by the level of serum inorganic phosphorus.[9] From these concepts it would follow that the lowered serum phosphorus level resulting from aluminum gel therapy would depress parathyroid hormone secretion and thereby enhance the renal resorption of phosphate.

Albright, F.; Bauer, W.; Cockrill, J. R., and Ellsworth, R.: Studies on the Physiology of the Parathyroid Glands: II. The Relation of the Serum Calcium to the Serum Phosphorus at Different Levels of Parathyroid Activity, ibid. **9:** 659-677 (Feb.) 1931.

However, if any such depression of parathyroid function does occur from chronic use of aluminum hydroxide gels, it is readily reversible, since there is a prompt restoration of the control serum and urinary inorganic phosphorus levels on cessation of therapy.

3. *Evaluation of Clinical Results of Aluminum Gel Therapy.*—Twenty-two patients have been followed at frequent intervals for two to seven years while they were on a moderately low phosphorus intake and receiving aluminum gels in amounts adequate to maintain the 24-hour urinary phosphorus excretion at low levels.[10] The periods over which this therapeutic regimen has been employed are given in table 2. Table 3 details the number of operations for removal of renal calculi in the group under study, prior to the institution of therapy. All the patients had had some type of phosphatic stone. Four had pure calcium phosphate calculi; the remainder had mixtures of calcium, ammonium or magnesium phosphatic stones. In several there were also admixtures of calcium carbonate and calcium oxalate. The four patients without previous operation had passed phosphatic stones.

Urinary cultures were made in all instances, with the results presented in table 4. Ten of the patients had urinary tract infections with either Bacillus pyocyaneus, Aerobacter aerogenes or Proteus vulgaris. In the 9 patients with positive urinary cultures for Staphylococcus albus, Staphylococcus aureus or Streptococcus, the significance of the culture was questionable because of the absence of microscopic evidence of urinary tract infection. In the presence of renal stones chemotherapy is notoriously ineffective. Except for brief courses of unsuccessful chemotherapy in 4 cases, no attempts were made to treat the urinary tract infection. The coincidence of chronic urinary tract infection with ammonia-forming organisms in approximately half the patients presented an additional difficulty for which other therapeutic regimens, such as the use of acidifying agents, are admittedly inadequate.
